e have emphasised that the beneficent development application of medical knowledge and skill, in trast to many other forms of science, are not an accident but have been possible because they have been handed on in a great moral and educational tradition, where certain standards of right and wrong in relation to the proper handling of human beings, which were the more powerful for being only semi-consciously held, were accepted and enforced by a strong public opinion. That moral and educational tradition is still strong, despite what the Nazis and others have done; but it is sharply challenged and quietly undermined within the profession, and the standards of public opinion have become equivocal. So far from the public demanding a certain moral and intellectual standard from the profession, it frequently looks anxiously to the profession for a lead and is sharply critical of it if it does not provide one. In such a situation, with medical knowledge, power, and prestige still growing rapidly, we dare not have doctors who are spiritual illiterates or moral savages, any more than we can have doctors who are quacks or charlatans.

The suggestions which follow do not claim to be either original or exhaustive. Also they are very generalised and will not apply with equal force in all situations. Yet they do indicate some of the places where Christians who are anxious to maintain and develop the great traditions of medicine can throw in their influence with particular confidence.

A GENERAL EDUCATION

First, it is a matter of urgent necessity that the medical student should receive a much better general education than he often does at present. How this is to be accomplished is a technical question of great complexity, involving a reconsideration of, among other things, the school examination system. It seems clear, however, that it is bad for the medical student to specialise in scientific studies closely related to medicine quite so early in his schoolboy career as he is normally expected to. Many would argue in favour of abolishing the arrangement by which the first M.B. examination can be taken in school, and of lightening the preclinical course to allow the student to look around and assimilate more of what the wider life of the university has to offer him.[4] In particular, many doctors complain that the loading of the student's memory with a mass of detailed information about such subjects as botany and zoology prevents him from receiving training in that synoptic approach to his studies which is peculiarly important for the doctor. They would cordially support the categorical statement of the Goodenough report that "throughout the course the main emphasis should be on the inculcation of fundamental principles and methods, rather than on the implanting of a mass of purely factual knowledge, much of which the student will soon forget" and that a ruthless pruning of the curriculum is urgently necessary. This can be done without seriously weakening the quality of the factual discipline provided by medical training.

One practicable arrangement, which has obtained for a very long time in the Scottish universities, is to offer a combined degree in arts and medicine, which is so organised as to enable the student to complete it in a shorter time than if he read for both degrees separately. Alternatively, as the Goodenough report suggests, special inducements should be offered to students who *have already graduated in other fields to study medicine.* Obviously it would be impossible for more than a small minority of students to undertake such courses, but even if as few as 1% of doctors did so—and presumably they would be among the abler students who would be likely to arrive at positions of leadership in the profession—it might make a great deal of difference to the whole tone of the profession's work and set the unmistakable stamp of a genuinely learned profession upon its work.

[4] The B.M.A. report, entitled The Training of a Doctor (London, 1948), has many useful and practical suggestions to make on this point.

CONTACTS

Secondly, the medical student needs active encouragement to make closer contact with the members of other faculties in the university. Medicine is an absorbing subject, and the average medical student suffers little from the apathy which affects students in other faculties. Medical "shop" is the most fascinating form of "shop," and medical students find it notoriously difficult to talk about anything but their own medical experience. To live with and to share in the interests of other students is a great safeguard against the dangers of this, as well as being of great benefit to the other students.

The measure of contact medical students have with members of other faculties varies considerably from university to university. In Oxford, it is very close. In places like Edinburgh and Birmingham it can be fairly close if the student takes advantage of the opportunities open to him. In the London medical schools, with the partial exceptions of University College and King's, it is generally non-existent. It is hard to see how medical education can claim to be university education when the student is deprived of one of the primary requisites of such education—intellectual and social coöperation with scholars pursuing different studies. This is a serious enough state of affairs on the undergraduate level. What is even more alarming is the fact that often such coöperation does not exist on the professional level either. In London, for example, most members of the staff of medical schools never have occasion to meet other teachers in the university at all.

THE PARTS AND THE WHOLE

Thirdly, students should be trained to see their subject as a complete unity, with the relation of its different parts to each other and to other branches of knowledge defined. Even the first of these is often not properly done, partly owing to the growth of specialisation. "The bearing of anatomy and physiology and the other basic sciences on clinical studies has been obscured, while the latter have tended to be conducted in watertight compartments, frequently in a more or less haphazard order," says the Goodenough report. The second has hardly been attempted at all. Yet the relation between medicine and the physical and biological sciences, anthropology and sociology and geography and psychology, philosophy and theology, is clearly of the greatest importance, and can hardly be indefinitely neglected if medicine is to retain its right to be considered a learned profession.

MORAL ISSUES

Fourthly, medical students should receive much more systematic and responsible guidance than they receive at present about how to deal with the familiar moral issues which arise so frequently in connexion with their work. This is not necessarily to claim that Christian views, in so far as they are well defined on such matters as euthanasia, abortion, and artificial insemination, should be taught to students as authoritative. But it is to claim that students should be made familiar with these views, in lectures at least as carefully prepared as any others that they receive, and encouraged in the responsible and critical discussion of them. Christian medical teachers, whose number is far from negligible, have a special responsibility to see that this is done. To say that it is inappropriate that these controversial issues should have a place in the medical curriculum is simply to say that the medical school is unable to provide a comprehensive preparation for medical practice, since these issues constantly arise in practice. The same holds with ever-increasing force in modern society of the teaching of the ethics of certification.

THE SENSE OF VOCATION

Fifthly, and above all, medical education sho to inspire those who undertake it with a sense of vocation and of belonging to a great professio high standards of public service and personal in which it is the specific duty of each doctor to end to maintain. This is especially true in these days, students often come forward for training with motives and a more highly developed sense of privileges than of their responsibilities. Here, of the personal influence of the teacher is the most im factor, especially on the clinical side, and the respo of teachers in these matters cannot be overemp Not least important in a comparatively lucrativ fession such as medicine is the necessity to students of the snare of wealth. What Prof. Polanyi has said to scientists in general has its p application to doctors: "The success of a man is measured by the amount of money he The success of a scientist should be measured amount of money he refuses to earn."[5] In th nexion it is important that medical schools the and not merely the small religious groups most int should remind students of the possibilities of in and the contribution to medicine made by missions.

With modifications and developments along suc a medical education could become what, at its is not far from becoming even now, one of the forms of general education that are availabl along with its existing virtues, it can provide a cultural background, a stronger sense of soci personal responsibility, and a training in deeper sensitivity, it will indeed be equipped to pro generation of doctors who will be more clearly th among the most useful of all servants of humanit

Public Health

Poliomyelitis

In the week ended Aug. 13 notifications in Engl Wales were: poliomyelitis 236 (164), polioencep (22). Figures for the previous week are shown in pare Notifications in the corresponding week of 1947 were myelitis 568, polioencephalitis 56.

Counties with multiple cases (poliomyelitis an encephalitis together) were: London 30 (31), Bedfo Berkshire 2 (3), Buckingham 2 (1), Cambridge 2 (0), 3 (3), Cornwall 6 (9), Devon 9 (6), Dorset 2 (1), Durha Essex 19 (7), Gloucester 7 (5), Hereford 4 (0), Ke Lancs 23 (12), Leicester 4 (5), Middlesex 10 (15), Norf Northampton 2 (0), Northumberland 4 (1), Nottingha Somerset 4 (2), Southampton 13 (9), Stafford 4 (2) 7 (7), East Sussex 5 (2), West Sussex 4 (2), Warwic Wiltshire 2 (2), Yorks, East Riding 2 (2), Yorks, West 34 (17), Glamorgan 3 (5), Monmouth 4 (2).

India Decides on Opium Prohibition

At a conference of provincial and State excise minist in Delhi early in August, Dr. Matthai, Indian finance stated that the policy of the central government was re of local consumption of opium to scientific and medi poses and prohibition of oral consumption of the r and of opium smoking. The meeting was conv formulate plans to reduce cultivation, production, an of the drug. It decided on total prohibition of opiu Indian Union in the next ten years except for purposes. Every year from now on there will be a con reduction by 10% of provincial and State requiren opium, based not on demand but on the minimum necessary to meet the needs of addicts and for medi A census of addicts is to be taken soon in each consumi It is also proposed to reduce the supply to addicts annually so that at the end of the decade oral cons will be virtually wiped out.

The long vacation course in nentary clinical methods for undergraduates has n completely reorganised to cover adequately the rmediate period between preclinical and clinical k in accordance with the recommendations of the neral Medical Council. Undergraduates also have the opportunity of attending an introductory course in psychology during the last long vacation term of their residence.

London Schools

LONDON UNIVERSITY bears a different relation to its medical faculty from other universities: whereas they have one school of medicine each, London has twelve autonomous schools, each of which is closely linked with one of the teaching hospitals, as well as University, King's, and Queen Mary Colleges, all of which take medical students for some part of the preclinical course. All the medical schools are now open to men and women students.

The preclinical course at UNIVERSITY COLLEGE is based on the belief that medical and dental students are best prepared for their future life by education of a university type. This principle is being put into practice by introducing various courses and classes whose aim is to provide an understanding of scientific and logical method and practice in the use of these. Experience shows that students do not learn these things unless they are specially taught how to do so, and the faculty is very conscious of the need for defining the aims of preclinical studies and investigating the methods of achieving them.

KING'S COLLEGE has in its medical faculty one of the largest schools for preclinical studies in London. Its members share fully in the social and athletic activities of students from all six faculties of the college. Clinical studies are pursued at King's College Hospital, St. George's, or Westminster. Arrangements are made by which patients attend the college for clinical demonstrations in applied physiology given by clinicians. Hostel accommodation for a limited number of men is available at King's College Hall, Champion Hill, S.E.5.

The arrangements made by the joint committee of QUEEN MARY COLLEGE and the London Hospital Medical College are working efficiently; and now that Queen Mary College holds its own special internal first examination for medical degrees the teaching subcommittee has organised the instruction in physics, chemistry, and biology to fit in closely with preclinical teaching. All available places are taken by London Hospital men and women; during the 1948–49 session 76 first medical and 12 premedical (Conjoint) students passed through the departments.

UNIVERSITY COLLEGE HOSPITAL and UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL are gradually settling down under the new system of dual control. It is often felt, however, that some less formal machinery should exist for coöperation between the teachers in the school and those in charge of patients in the hospital, considering that they are often the same people. Students are beginning to benefit from the facilities of the St. Pancras "wing"; they find valuable clinical material among the aged and chronic sick and are now attending regular demonstrations in the mental observation unit. The London Hospital for Tropical Medicine is now an integral part of the U.C.H. group, so postgraduate clinical teaching in tropical medicine will be included in the group's activities.

The Medical College of ST. BARTHOLOMEW'S HOSPITAL is steadily recovering from the disorganisation caused by the war. The selection of new students from the very large number of candidates has in itself become a major problem. To increase the entry would lead to overcrowding; and much time has to be spent in interviewing the many hundreds from whom each year no more than 100 students can be chosen. This work is done by a committee, which considers the new entry one year in advance and completes the main part of its work between October and February. With each advance in science the undergraduate curriculum tends to become more and more congested. Recent attempts at simplification have met with some success. In the preclinical years the institution of internal university examinations has gone some way to prevent the students' work becoming *too diffuse. By a firm allocation of the major part of the* clinical students' time to general medicine and surgery, it has been possible to ensure that the many exacting and rapidly developing branches of medicine do not so encroach on their limited time that the wood is obscured by the trees. The effort to ensure that the very large numbers of undergraduate students do not get lost in the thickets of modern medicine and its applied sciences leaves little time to give formal teaching to postgraduates; nor does the college attempt this on a major scale. A course for the final fellowship is held twice a year and is limited to 25 students. A course for the primary fellowship is held at similar intervals.

The new extensions to the school at CHARING CROSS HOSPITAL have now been in use for two years; they are providing most satisfactorily for the preclinical students. Last March, for the first time, an internal second M.B. examination was held in the school and the results were most gratifying; of the 44 candidates, 38 satisfied the examiners in anatomy and physiology and were able to begin the introductory clinical course in April. The facilities of the school and hospital are practically restricted to undergraduate students. The only postgraduate training provided is for old students returned from National Service who are working for higher qualifications, and in the radiology department where three students are admitted each year for part 2 of the D.M.R. or D.M.R.-D. courses. The plans for the new hospital and medical school to be built on the Northwick Park site at Harrow have now been submitted to the Ministry of Health and to the university.

ST. GEORGE'S HOSPITAL, with 130 clinical students, is one of the smaller schools. The firms are small; the number in each is approximately 8. Women have been accepted for training since 1945; they have done extremely well. The principal factor limiting intake is the size of the pathology laboratory, which can accept at the most 40 students. The new midwifery department has a large enough turnover to provide all the cases needed by undergraduates. Introductory courses to link anatomy and physiology with clinical work are held; these include instruction in methods of examination, and emphasis is placed on the normal and variations in the normal.

At GUY'S HOSPITAL Medical School the aim has always been to encourage students to accept responsibility as early as possible, rather than to spoon-feed with too much organised teaching. There are, however, lectures and demonstrations organised by the directors of the departments of surgery, medicine, obstetrics, pædiatrics, and anæsthetics in order to cover the whole curriculum. The object is to make good doctors rather than good examination candidates. There is a full range of house-appointments for which students may apply when they qualify, and every encouragement is given to men of promise to obtain the higher degrees and diplomas. House officers, and students during selected weeks of their course, live in the college; and there are two hostels where a limited number of senior students can live near the hospital. It is a condition of entry to the medical school that students should join the clubs' union which covers all athletic and intellectual activities and includes membership of the students' club.

KING'S COLLEGE HOSPITAL Medical School provides the clinical training for men and women students reading for the medical degrees of the Universities of Oxford, Cambridge, and London. The preclinical course for students reading for the University of London degrees of bachelor of medicine and bachelor of surgery is taken in the faculty of medical science at King's College, Strand, where students are admitted once a year, in October, and have the advantage of working for the first two to three years of the course in association with students of all university faculties. Students are admitted for clinical training twice a year, in April and October. The medical curriculum is at present being revised, and will in future include the teaching of psychological medicine and certain special subjects such as orthopædics and urology during the first twelve of the clinical course. Three months will be entirely to the study of pædiatrics, including 14 *residence at the Belgrave Hospital for Children* sion course will be held twice a year immediately p the M.B., B.S. examinations. The museum re-catalogued and many of the specimens re New teaching specimens are regularly being special feature is being made of post-mortem de tions, and the post-mortem department ha re-equipped to provide for this. Library facilit been increased, and provision has been made undergraduate and postgraduate work. An weekend postgraduate course, open to former of the school and to local medical practitioners annually in October.

Apart from instruction in tuberculosis and m all teaching at the LONDON HOSPITAL is cent the hospital itself. The tutorial system by whi student is allocated to one of the first assista acts as his tutor, is working satisfactorily. Tl ductory course, designed to help students in the t from preclinical to clinical studies, continues a great success. By a system introduced during year, all students are on duty in the wards weeks during their clinical training. This "bac patient" movement has so far succeeded ve Students are on duty for five hours on ordinary w and three hours on Saturdays, choosing their ow to fit in with their lectures and the requiremen ward in which they are working.

At ST. MARY'S HOSPITAL Medical School a biochemistry has been instituted. In view of the i number of students and in order to strengthe graduate teaching, readerships are being estab anatomy, physiology, pharmacology, and bact For the second year, a certain number of stud have passed their 2nd M.B. examination ha selected to take a special honours B.SC. degree in or physiology before commencing their clinical A revised course of clinical lectures lasting t has been introduced. It is expected that this wi assist the clinical students to cover the systematically. All students who have attaine ciently high standard in their final examina given special opportunities of studying for highe and diplomas. In order to encourage original w postgraduate research fellowships are awarded During the past year new research laborator been equipped in the biochemistry department medical unit. A new common-room for women a new kitchen for the students' restaurant, and graphic department for the use of the medic and hospital have been opened.

The MIDDLESEX HOSPITAL has now been fully for more than a year, and in fact there are n beds for teaching than before the war. Faci instruction in the clinical period are enhanced the majority of students being attached to the Middlesex Hospital, Willesden, for at least three instruction. Two improvements in the clinica have been recently introduced. Students no three weeks' resident instruction in infectious at the North Eastern Hospital; and sti recently students have been enabled to visit Hospital for instruction in pulmonary tubercul *important step forward* has been taken by the in increasing the number of registrars. This mo more men can receive postgraduate instructio view to becoming consultants or specialists.

The ROYAL FREE HOSPITAL School of Me now a coeducational school, and accepts betw and 500 students. There will be no entrance exa for the 1950–51 session, and candidates will be by an interviewing committee. An arrangem recently been made for the sharing of social an tional clubs between the students' union of th and the students' union of Guy's Hospital Medica A new wing, to include additional laboratories, rooms, cloak-rooms, &c., is being added to th building in Hunter Street to accommodate the i

s. Clinical teaching is given throughout the ls associated with the Royal Free Hospital group, as over 700 teaching beds.

ng the past year ST. THOMAS'S HOSPITAL Medical has become a corporate body. Good progress ery from the chaos of war has continued, and much ruction has been accomplished. Laboratory as been increased by the utilisation of basements, new photographic unit opened, The hospital has er 500 beds open apart from others available in ated hospitals. With the opening of a new tempor- partment, outpatient teaching is conducted under improved conditions. The chairs of anatomy edicine have been filled by new appointments, and lership in therapeutics established. The final course has proved its worth both to old Thomas's nd to candidates from the Dominions. This at t affords the only postgraduate teaching for outside nts; the number of beds is insufficient for both aduate instruction and a full undergraduate . A very successful series of clinico-pathological ngs, on the lines of those held at the Massachusetts al Hospital, has taken place with many well-known ans as guest speakers. The new metabolic research s nearing completion, and this year the school has over the direction of all clinical pathology in the al. Student life is thriving in a wide field of ties, with outstanding victories in sailing, squash ts, and bridge. It is hoped that the new athletic d at Cobham will help to bring success in other of sport.

has been agreed that the WEST LONDON HOSPITAL al School shall join the British Postgraduate al Federation as soon as it is in a position to accept graduate students for training as medical and cal specialists. The school is not taking any more rgraduate students, the last entry having been in ber, 1948, and probably the first postgraduate ents will be admitted in January, 1950. Since the ol is to fulfil its obligations to all its present under- uate students, it will not be able to devote its full irces to postgraduate teaching until 1952. The ils of the postgraduate training have not yet been ed out: but it is known that the university requires hool for the training of general physicians and general eons, and this work will be allocated to the West don Hospital Medical School. As far as possible, the ing will involve practical work in the wards and atient department, and in the early stages of training students will be attached to the physicians and eons as medical and surgical "firms," with duties lar to those at present carried out by undergraduate lents.

his year the WESTMINSTER MEDICAL SCHOOL has brated its centenary. All old students were invited elebrations extending over three days and including ief course of postgraduate lectures given by members the staffs of the Westminster group of hospitals. s year, too, an F.R.C.S. course is to be held for the time at Westminster and the designated hospitals. course—one of eight weeks beginning on Sept. 6— imited to 20 postgraduate students. The number undergraduate students has mounted steadily to the sent total of 140, and the problem of selection from enormous number of applications is becoming reasingly difficult. The clinical facilities at the ignated hospitals make it possible for an increasing ount of instruction to be given outside Westminster spital itself and thus to deal more easily with the wing number of undergraduates. Students on general ns already attend All Saints' Urological Centre; the diatric firm is at Westminster Children's Hospital, d a new surgical firm will shortly be formed to work the Gordon Hospital. The teaching of psychiatry s been reorganised. There is a resident course on ectious diseases at the Western Hospital. A fort- ght's resident course for final-year students has been stituted at King Edward VII Sanatorium, Midhurst, ere the students attend in groups of four. Only in e teaching of pathology has the problem of over- owding arisen, and this has been solved by spreading instruction in that subject over a longer period of the clinical course. The school has recently acquired a new sports ground at St. Ebba's Mental Hospital, Epsom.

At the SCHOOL OF DENTAL SURGERY of the ROYAL DENTAL HOSPITAL of London, the curriculum for the first two years includes the study of dental mechanics, dental prosthetics, the properties of dental materials, general anatomy and physiology, and special anatomy and physiology. The anatomy and physiology courses are held at King's College in the Strand. For the second two years students attend lectures and clinics on general medicine and surgery at Charing Cross Hospital Medical School, and lectures and practice in dental surgery at the dental school.

Other English Schools

At the UNIVERSITY OF DURHAM competition for admission to the medical school has been more intense this year than at any time since the war. The vast majority of candidates have applied for admission to the second-year course, in which there will not be more than 30 vacancies. Women students are being accepted in the approximate proportion of one to every four men. This means that although there is no fixed quota for women there is nevertheless intense competition for the places available, and over-all it is estimated that this year it will be possible to admit about one candidate in ten. The university have been compelled to make drastic reductions in the number of first-year students this year, in order to ensure that next year there will be more vacancies to meet the greatly increased demand by well qualified candidates for places in the second year. It may prove necessary next year to dispense altogether with the first-year course. In undergraduate teaching the present arrangement of holding the 2nd M.B. examinations in anatomy and physiology as separate parts is to be discontinued. In 1951 there will be a return to the system whereby the examinations in anatomy and physiology are taken together after five terms' work, to form part I of the 2nd M.B. examination. A rearrangement of the final examination will also take place in 1950–51. Surgery is to be taken in part II of the final examination in June of the final year, in company with medicine and pædiatrics. Midwifery and gynæcology remain as part I of the examination taken in the previous December.

At the UNIVERSITY OF BIRMINGHAM * the increased number of students has enforced duplication of practical classes in the preclinical years. This has caused further embarrassment to the depleted staff. The experiment of teaching anatomy and physiology as an integrated subject continues to attract great attention and has earned the congratulations of other medical schools. The innovation of encouraging honours B.SC. students to carry out original investigations as they extend their knowledge of the basic subjects has also proved a success, and substantial contributions to research have already been made by this means. The anatomical and dental museums are being reconstructed so that self-explanatory demonstrations may be presented to students from time to time. By a redistribution of space, greatly increased accommodation has been provided for the teaching of surface anatomy. The building of the experimental anatomical research laboratory is proceeding slowly. On the clinical side the regional hospital board has given many examples of its desire to coöperate with the university by providing members of the university teaching staff with opportunities for practice and for teaching undergraduates and postgraduates in hospitals under its authority. A standing joint committee consisting of representatives from the university, the board of governors of the teaching hospital, and the regional hospital board has been formed to ensure this close collaboration. A new departure in the department of bacteriology is the introduction of an honours (B.SC.) school which will help to meet the urgent need in

---

* The entrance requirements for the Universities of Manchester, Liverpool, Leeds, Sheffield, and Birmingham are laid down in the pamphlet, *University Entrance Requirements 1951–1955,* copies of which may be obtained from the Secretary to the Joint Matriculation Board, 315, Oxford Road, Manchester, 13. The pamphlet also includes the requirements in force up to 1951. Additional faculty requirements may, however, be imposed: details can be obtained from the dean of the faculty of medicine in each university.

and it is hoped that construction will start this year. A full-time medical officer in charge of students' health has been appointed, and all first-year students are required to be medically examined. This examination consists of (*a*) general physical and clinical examination, (*b*) Mantoux test, and (*c*) chest X ray. The examination must be repeated before entering upon clinical studies.

The NATIONAL UNIVERSITY OF IRELAND has colleges in Dublin, Cork, and Galway.

At UNIVERSITY COLLEGE, DUBLIN, the number of applicants for entrance appears to be falling slightly, but the demand is still very heavy. During last year brief courses, intended for general practitioners, were held in special branches of medicine—pulmonary culosis and venereal disease. Although the a was small, the college is so convinced of the of courses of this kind that similar arrange being made for the coming year.

At UNIVERSITY COLLEGE, CORK, an entrance tion in chemistry and physics must be passed by entering for the premedical course, by a which came into force in 1948.

At UNIVERSITY COLLEGE, GALWAY, students pass the premedical examination within two starting the course; and they must pass the second medical examinations within two years of the previous examination.

Degrees and Diplomas

EXAMINING BOARDS

English, Scottish, and Irish Conjoint Boards

THE Examining Board in England of the Royal College of Physicians of London and the Royal College of Surgeons of England examines candidates for the qualifying diplomas of L.R.C.P., M.R.C.S. Candidates satisfying the board's regulations in regard to the preliminary examination in general education are eligible for admission to the premedical examination in chemistry, physics, and biology, and are required to complete the professional curriculum subsequently at a recognised medical school. New regulations, published in 1948, apply to all new entrants and certain others, and will apply to all candidates from Sept. 1, 1950. Under emergency regulations, introduced in the war, the medical course is reduced from 57 to 54 months, and candidates are admissible to the last subject of the final examination after 30 months of clinical study instead of 33. The regulation permitting a candidate to enter for one part of the final after 24 months of clinical study still holds. Some other war-time concessions are still authorised in the regulations; for example, clinical study may be undertaken at any hospital provided the dean of the candidate's school is satisfied as to the instruction available and signs the certificate of study. Other modifications will be found in the emergency regulations, copies of which, with a calendar showing the dates of examinations, may be obtained, free of charge, from the secretary to the Examining Board in England, the Examination Hall, Queen Square, London, W.C.1.

The Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Royal Faculty of Physicians and Surgeons of Glasgow have an arrangement by which, after one series of examinations, held in Edinburgh or Glasgow, or both, the student may obtain the diplomas—designated by the letters L.R.C.P.E., L.R.C.S.E., L.R.F.P.S.G.—of all three bodies. Candidates may work for the examination of the Scottish Conjoint Board at any of the recognised medical schools of Great Britain and Ireland. The course lasts six years and includes, in addition to the preliminary examination in the natural sciences—i.e., chemistry, physics, and biology—three professional examinations: the first in anatomy and embryology, physiology, biochemistry, and biophysics; the second in pathology and bacteriology and pharmacology; and the final in medicine, surgery, midwifery, forensic medicine, and public health. Details may be had from the registrar, 18, Nicolson Street, Edinburgh.

The Conjoint Board of the Royal College of Physicians of Ireland and Royal College of Surgeons in Ireland accepts candidates for the L.R.C.P.I. and L.M., L.R.C.S.I. and L.M. from most of the recognised medical schools at home and abroad. Full details of the regulations can be obtained from the registrar, Royal College of Surgeons in Ireland, Dublin.

Apothecaries' Licences

The Society of Apothecaries of London grants the L.M.S.S.A. Lond. to candidates who pass the primary examination (which is held quarterly) and the final examination. Final examinations are held except in September. The minimum period of is *normally five years. The four parts* of the examination may be taken together or in any Regulations and a schedule of the required co study may be obtained from the registrar, Apo Hall, Black Friars Lane, E.C.4.

The Apothecaries' Hall of Ireland grants the L.A.H. Dubl. to students who have passed the professional examinations. Intending candidates furnish evidence of having attended an approved *in practical and theoretical pharmacy.* The confers on holders the right of registration Medical Registers of Ireland and Great Britain nations are held three times yearly, in March, J November. Further information may be had registrar, 95, Merrion Square, Dublin.

UNIVERSITY DEGREES

Bachelor of Medicine and Surgery

All the universities in the United Kingdom, Nottingham and Reading, offer baccalaureate in medicine and surgery, conferred on the examination.

HIGHER QUALIFICATIONS

Those who have graduated in medicine and s at liberty to seek higher qualifications if they wish

Doctor of Medicine and Master of Surgery

Graduates holding a bachelor's degrees can t degree of doctor of medicine or master of surgery universities with medical faculties in Great Brit Ireland confer such degrees. London University the M.D. in general medicine, and in pathology, p logical medicine, midwifery and diseases of hygiene, and tropical medicine; the M.S. is obtain general surgery, and in dental surgery, ophtha and laryngology, otology, and rhinology. *At the* U sity of Durham the degree of doctor of surgery (is offered in addition to the degree of master of s (M.S.). Liverpool offers the orthopædic degre M.CH. ORTH.

Master in the Science of Obstetrics and Mast Midwifery

The Irish universities grant the degree M.A.O Society of Apothecaries of London grants the m of midwifery (M.M.S.A.) upon examination in obst pædiatrics, and public health. The examination held in May and November, and regulations ma obtained from the registrar, Apothecaries' Hall, Friars Lane, E.C.4.

MEMBERSHIP AND FELLOWSHIP

The Royal College of Physicians of London the membership (M.R.C.P.), which is obtained examination. Examinations are *held four times* in year, and medical graduates and licentiates of the over twenty-three years of age may sit for it. Detai be obtained from the Secretary, Royal Colle Physicians, Pall Mall E st, London, S.W.1. Fello

ege are elected annually at a general meeting
ollege.

Royal College of Surgeons of England grants a
ip to those passing the primary and final F.R.C.S.
tions. The primary examination is open to
ho hold a qualification registrable in the British
Register and to graduates in medicine and
of universities and medical colleges recognised
council. Subjects of the primary examination
atomy (including normal histology), applied
gy, and the principles of pathology. The final
ation can be taken in general surgery, ophthal-
or otolaryngology. To be admitted to the final
ation in general surgery candidates must produce
e of having been engaged in acquiring professional
lge for not less than three years after taking a
sed medical qualification, and of having held the
e resident surgical posts during a part of that time.
ates for the final examination in ophthalmology
aryngology must have been qualified for three
nd must have held general and specialist resident
uring an aggregate period of eighteen months.
mary examination is held in January and July;
final examination is held in May and November.
llege also grants a fellowship in dental surgery.
imary examination is open to those with a dental
ation registrable in the British Dentists Register,
graduates and diplomates in dental surgery
iversities and licensing bodies recognised by
uncil. Subjects of the primary examination are
l anatomy, and applied physiology and the
les of pathology, with special reference to the
and jaws, and of the final examination surgery,
athology and bacteriology, and dental surgery.
of the regulations and full particulars may be
ed from the examinations secretary, Examination
Queen Square, London. W.C.1.

ical graduates who have been registered, or
e for registration, for at least three years may
for examination for membership of the Royal
e of Obstetricians and Gynæcologists (M.R.C.O.G.).
ulars of the regulations may be obtained from
ecretary, Royal College of Obstetricians and
ologists, 58, Queen Anne Street, London. W.1.
fellowship (F.R.C.O.G.) is granted to members
re judged by the council to have advanced the
e and art of obstetrics and gynæcology.

duates may become members of the Royal College
ysicians of Edinburgh (M.R.C.P.E.) on passing an
nation, particulars of which may be obtained from
ecretary, 9, Queen Street, Edinburgh, 2. The
s are selected from among the members by the
il of the college, and receive the designation
P.E.

lowship of the Royal College of Surgeons of Edin-
(F.R.C.S.E.) is granted to medical graduates who
the required examinations. Under new regulations
come into force at the beginning of next year the
ination will be divided into two parts—the first
natomy and physiology and on pathology and
riology, and the second on the principles and
ice of surgery and on one of four special subjects
chosen by the candidate. Unsuccessful candidates
appeared for examination on or before March 15
ear may still elect to be examined under the existing
ations. Particulars of the regulations may be
ned from the clerk of the college, Surgeons' Hall,
icolson Street, Edinburgh.

e Royal Faculty of Physicians and Surgeons of
gow grants, after examination, a fellowship *qua*
ician and a fellowship *qua* surgeon registrable by
G.M.C. as an additional qualification (F.R.F.P.S.G.).
ission is by examination and subsequent election.
lidates for the fellowship in medicine must have
in possession of a recognised medical qualification
ot less than three years, and must have been engaged
ng one of these years in full-time clinical work in a
gnised hospital and have spent two other post-
uate years in approved medical work. The examina-
comprises a clinical examination in medicine, written and oral examinations in the principles of medicine and medical pathology, and written and oral examinations in the practice of medicine and therapeutics. Candidates for admission to the fellowship in surgery are required to possess a recognised medical qualification and to pass a primary and a final examination. The primary examination consists of written and oral examinations in anatomy, physiology, and pathology and bacteriology. For admission to the final examination candidates must have been in possession of a recognised medical qualification for not less than three years and produce evidence that they have been engaged, after qualifying, for one year in full-time clinical work in a hospital approved by the council and for a further two years in the study of surgery. The final examination comprises a clinical examination in surgery, written and oral examinations in surgical anatomy and surgical pathology, and written and oral examinations in surgery. Alternatively, candidates may submit themselves for examination in one of the following subjects: obstetrics and gynæcology, ophthalmology, or otorhinolaryngology. Details may be had from the secretary of the Royal Faculty of Physicians and Surgeons, 242, St. Vincent Street, Glasgow, C.2.

Membership of the Royal College of Physicians of Ireland (M.R.C.P.I.) is granted on the result of an examination, the details of which may be obtained from the registrar of the college, 6, Kildare Street, Dublin. Fellows are elected by ballot from among the members, and receive the designation F.R.C.P.I.

Graduates seeking the fellowship of the Royal College of Surgeons in Ireland (F.R.C.S.I.) must pass in two examinations, a primary in anatomy, physiology, and the principles of pathology, and a final in surgery. Further particulars may be obtained from the registrar, the Royal College of Surgeons in Ireland, Dublin.

The Faculty of Radiologists offers a fellowship (F.F.R.) to medical graduates of five years' standing who have spent at least one year in general clinical work at approved hospitals, hold a radiological diploma, and have practised radiology exclusively for at least two years after obtaining that diploma. Candidates are required to pass an examination and submit a thesis. Candidates who hold higher medical or surgical qualifications may be exempted from the examinations in general medicine, general surgery, or pathology. Full particulars may be obtained from the warden, the Faculty of Radiologists, 45, Lincoln's Inn Fields, London, W.C.2.

SPECIAL DEGREES AND DIPLOMAS

The regulations for the following diplomas can be obtained by applying to the examining bodies concerned.

Anæsthetics

The English and Irish Conjoint Boards offer diplomas in anæsthetics (D.A.).

Bacteriology

Diplomas in bacteriology are granted by the universities of London and Manchester.

Child Health

Diplomas in child health (D.C.H.) are granted by the National University of Ireland and the English and Irish Conjoint Boards.

Clinical Pathology

The University of London offers a diploma in clinical pathology (D.C.P.).

Industrial Medicine

The University of Edinburgh, the Royal Faculty of Physicians and Surgeons of Glasgow, the Society of Apothecaries of London, and the English Conjoint Board offer diplomas in industrial health (D.I.H.).

Laryngology and Otology

The English Conjoint Board offers a diploma (D.L.O.) for those who have made a special study of the ear, nose, pharynx, and larynx. The final examination for the F.R.C.S. may be taken in otolaryngology.

Obstetrics and Gynæcology

The Royal College of Obstetricians and Gynæcologists grants by examination a diploma (D.OBST. R.C.O.G.) to graduates with postgraduate hospital experience in general medicine or surgery and in obstetrics. The University of Dublin also offers a diploma (D.G.O.). The higher qualifications granted by the Irish universities and the Society of Apothecaries of London have already been mentioned.

Ophthalmology

The English and Irish Conjoint Boards issue a diploma in ophthalmology (D.O.M.S.). The final examination for the F.R.C.S. may be taken in ophthalmology.

Orthopædics

Liverpool University offers the degree of M.CH. ORTH.

Physical Medicine

The English Conjoint Board offers a diploma in physical medicine (D.PHYS.MED.).

Psychological Medicine

The Universities of London, Belfast, Bristol, Durham, Edinburgh, Ireland (National University), Leeds, and Manchester and the English and Irish Conjoint Boards offer diplomas in psychological medicine.

Public Health

A diploma in public health (D.P.H.) is granted by the English Conjoint Board and by all the universities of the United Kingdom, except Cambridge, Oxford, Reading, *Sheffield, and Nottingham.*

Radiology

The Faculty of Radiology grants a fellowship (F.F.R.). The universities of London, Bristol, and Edinburgh and the English Conjoint Board offer two diplomas—one in medical radiodiagnosis (D.M.R.-D.) and one in medical radiotherapy (D.M.R.-T.). Liverpool University offers a new diploma (DIP. RAD.) obtainable by examination after a two-year course on diagnosis or therapy: after a further two years diplomates may be awarded the M.RAD. by presentation of a thesis.

Tropical Medicine

A diploma in tropical medicine and hygiene (D.T.M. & H.) is granted by the University of Edinburgh, by Liverpool University jointly with the Liverpool School of Tropical Medicine, and by the English Conjoint Board.

Tuberculous Diseases

Examinations for the diploma in tuberculous diseases (T.D.D.) of the University of Wales have been resumed.

DENTAL DEGREES AND DIPLOMAS

There are schools of dentistry at the universities of London, Belfast, Birmingham, Bristol, Dublin, Durham, Edinburgh, Glasgow, Leeds, Liverpool, Manchester, Sheffield, and St. Andrews; and at the University Colleges of Dublin and Cork, in the National University of Ireland. London University offers a B.D.S. and an M.S. in dental surgery; it also prepares students for the L.D.S. of the Royal College of Surgeons. This college has lately instituted a fellowship in dental surgery (F.D.S.) which is also to be instituted by the Royal College of Surgeons of Edinburgh. St. Andrews offers a B.D.S., and Edinburgh University an L.D.S. and a B.D.S. Leeds grants an L.D.S., a baccalaureate degree (B.CH.D.), and mastership (M.CH.D.). Glasgow University and the University Colleges of Dublin and Cork grant a B.D.S. and a M.D.S., and Trinity College, Dublin, offers a B.DENT.SC. and a M.DENT.SC. All the other universities mentioned offer L.D.S., B.D.S., and M.D.S.; St. Andrews offers also a diploma in public dentistry (D.P.D.). Licences in dentistry are granted by the Royal College of Surgeons of Edinburgh, the Royal Faculty of Physicians and Surgeons of Glasgow, and the Royal College of Surgeons in Ireland. The Royal Faculty of Physicians and Surgeons confers a higher diploma in dental surgery (H.D.D.) and a diploma in orthodontics (D.D.O.).

Postgraduate Education

In London

it board has been established to effect coöperation the BRITISH POSTGRADUATE MEDICAL FEDERA- niversity of London) and the three Royal in providing postgraduate education in the and dental specialties in London, supplementing ovisions at the undergraduate medical schools ching hospitals. Each of the three Royal colleges s courses of lectures in the clinical aspects of pecialties, and the Royal College of Surgeons s, in addition, courses of lectures and demonstra- n the basic sciences for potential surgical and specialists, and in anæsthetics. Each Royal provides expert advice and guidance on suitable l appointments and programmes of study for ates for its higher qualifications and other grad- isiting this country for further study, and the s of the staff of the central office of the federation ilable to all postgraduates.

British Postgraduate Medical Federation is a of the University of London. It includes the aduate Medical School at Hammersmith Hospital, ts university departments of general medicine, surgery, and pathology. and institutes in the al clinical branches of medicine associated with ecial hospitals. In addition to the Postgraduate l School, the institutes included in the federation hose of psychiatry, neurology, child health. lmology, laryngology and otology, diseases of the cardiology. orthopædics, dermatology. urology, ics and gynæcology, and dental surgery. These various stages of development. and the numbers lents that can be admitted to the clinical practice ne of the hospitals are limited. Appointments of ouse-officer and registrar types in the hospitals nstitutes provide the most valuable form of post- ate education, and there are opportunities for ch by selected graduates. At all the institutes s of instruction are given throughout the academic they are suitable for graduates in the early of their specialist education and also for those nave completed their practical training. Two or years of hospital work in general medicine and al surgery after graduation are normally advisable commencing work in the special branches. The at the institutes is of an advanced type and ficiently comprehensive to enable graduates with le practical experience to prepare for higher es and diplomas. Emphasis is placed on clinical and atory teaching, supplemented by lectures and nstrations.

Postgraduate Medical School of London is associated the Hammersmith Hospital, Ducane Road, W.12. It niversity departments in medicine, surgery. and patho- The teaching in the clinical departments, based on work, is continuous and is supplemented by lectures g three ten-week sessions starting in January, April, and er. A course for the university diploma in clinical logy, lasting one year, is available for a limited number lected students. The department of radiology of the tal provides courses for the diplomas in medical radiology e university and the Conjoint Board. All these courses in October. Long-term and short-term tuition in thetics is provided for a small number of students.

e *Institute of Cardiology* is associated with the National t Hospital, Westmoreland Street, W.1. Seven appoint- s of the registrar type are offered each year to physicians aining as cardiologists who already have a sound ground- n general medicine. General physicians may enrol for ime or part-time instruction for one term of approxi- ly three months. There are three terms annually, mencing in January. May, and October. Three intensive ses of lectures and demonstrations, each lasting a night, are held in February, July, and November.

he *Institute of Child Health* is associated with the Hospital Sick Children, Great Ormond Street, and the Postgraduate ical School at Hammersmith Hospital; the Queen abeth Hospital for Children, Hackney, also participates in the clinical teaching of the institute. The institute provides tuition throughout the year in three terms of three months each, commencing in January, May, and September, and in addition a series of lectures by specialists and experts in various spheres is given each term.

The *Institute of Dermatology* is associated with St. John's Hospital for Diseases of the Skin, 5, Lisle Street, W.C.2. Clinical teaching takes place in the outpatient department twice daily. There are also facilities for study and tuition in the pathological laboratory, but owing to the restricted accommodation no ward instruction is possible yet. A short course of lectures is given in the summer months, and a longer and more systematic course in the winter. Clinical assistantships are arranged for more advanced students.

The *Institute of Diseases of the Chest* is associated with the Brompton Hospital, S.W.3. Students enrol for three months or more on what is at present an approximately half-time course. In special cases a whole-time programme can be arranged. Courses consist of clinical work in wards and outpatient departments, lectures, and demonstrations. There are three terms annually, commencing in January, April, and October.

The *Institute of Laryngology and Otology* is associated with the Royal National Throat, Nose, and Ear Hospital at Gray's Inn Road and Golden Square, W.C.1. A comprehensive full-time course lasting twenty weeks is held twice a year, commencing in January and July. A part-time advanced revision course lasting 10–12 weeks, suitable for students preparing for the higher qualifications, is held twice yearly, approximately from February to May and from September to November. There are a number of appointments open to students, after completion of basic training in the specialty, which give good opportunities for acquiring and extending clinical experience.

The *Institute of Neurology* is associated with the National Hospital for Nervous Diseases, Queen Square, W.C.1. The teaching is mainly by attendance on the hospital practice, and there are three terms annually. More advanced students are appointed as clinical clerks in the wards or attached to special departments and the research laboratories. Two whole-time courses in clinical neurology are held annually in the autumn and spring terms. During the summer term there is a course in neurosurgery. Two courses of weekly clinical demonstrations are held regularly.

The *Institute of Obstetrics and Gynæcology* is associated with the Queen Charlotte's Maternity Hospital, the Chelsea Hospital for Women, and the department of obstetrics and gynæcology at the Postgraduate Medical School. The teaching is based on ward work and is supplemented by lectures and demonstrations during three ten-week terms commencing in October, January, and April. Short intensive courses of a fortnight's duration, held twice a year, are suitable for students preparing for the higher qualification. A limited number of posts suitable for junior specialists receiving advanced training is available.

The *Institute of Ophthalmology* is associated with the Moorfields, Westminster and Central Eye Hospital. In addition to teaching by means of hospital practice, a routine lecture and tutorial course, lasting 4–5 months, is held twice a year commencing in March and October. Clinical teaching and lectures are given at a higher level for advanced students.

The *Institute of Orthopædics* is associated with the Royal National Orthopædic Hospital, Great Portland Street, W.1. The practice of both the central hospital and the country hospital at Stanmore is open to postgraduate students. Selected students have opportunities for taking an active part in the work of the institute and the hospital and of spending in the institute up to two years of their training. A comprehensive basic course of six months' duration is held each year, commencing in October. Twice a year, in April and September, a one-week course in advanced clinical orthopædics is held.

The *Institute of Psychiatry* is associated with the Maudsley Hospital, Denmark Hill, S.E.5, and the Bethlem Royal Hospital. Training normally covers 2–3 years after experience elsewhere in general medicine, and is based on responsible hospital duties under supervision. Regular series of lectures and demonstrations are given throughout each of the university terms; clinical training continues throughout the year and includes seminars and case discussions. Students who, because of previous experience, do not wish to take the comprehensive two-year course will be able to attend limited series of lectures and clinical instruction. There are facilities for original investigations under supervision in the clinical departments and in the psychological, neuro-anatomical, electrophysiological, and biochemical departments.

The *Institute of Urology* is associated with St. Peter's and St. Paul's Hospitals, Henrietta Street, W.C.2. Three courses of fourteen weeks' duration are held annually, commencing in January, April, and September. An intensive two-week course suitable for students taking higher examinations is held in September and March. Limited numbers of clinical assistants are appointed in January and July each year. Two courses in venereology, each lasting four months, are held annually, commencing in April and September.

The *Institute of Dental Surgery* is associated with the Eastman Dental Clinic. The object of the institute is to train dental practitioners in the special branches of preventive and therapeutic dentistry, both for children and adults, by means of clinical experience, lectures, demonstrations, and research. Opportunities for limited numbers of students are available in orthodontics, conservative dentistry, periodontia, and preventive dentistry, the courses varying from four to twelve months in duration.

It is essential for prospective students to make their arrangements well in advance. Those sponsored by their universities, governments, or other official bodies receive first consideration in the allotment of vacancies. Established specialists from overseas, here for a relatively short time, who wish to see something of the practice of this country, are always welcome; they are regarded as visiting colleagues, and the experts in their specialties are always ready to receive them and let them accompany them in their work and teaching. In addition, refresher courses for general practitioners are arranged at non-teaching hospitals in London and the home counties. The federation has a central administrative office at 3, Gordon Square, London, W.C.1, to which inquiries should be directed. An information bureau of post-graduate activities in London and other university centres is maintained.

The **Royal College of Physicians of London** holds a series of advanced postgraduate lectures, including some on pathology, biochemistry, &c. The lecturers are drawn from the provinces as well as London. The audience is limited to 200. Details can be obtained from the Secretary of the College, Pall Mall East, London, S.W.1.

The **Royal College of Surgeons of England** has arranged a number of lectures and demonstrations to be held at the college. In surgery two series, each of 24 lectures, will be given during October and April, and at the same time clinical conferences will be arranged at selected hospitals. In anæsthesia two series, each of 45 lectures, will be given in October and March; in addition courses extending over a period of from one to two years are being arranged. Between October and January, and also between March and May, there will be a series of 72 lectures and practical demonstrations in anatomy, applied physiology, and pathology. Lectures in oral, dental, and general surgery will be held in February–March; and lectures and practical demonstrations on the application of the basic sciences to dental surgery will be held in July and January–February. Lectures and courses are arranged during the year jointly with the Institute of Child Health, the Institute of Laryngology and Otology, and the Institute of Urology. Specialists are available for consultation on postgraduate training in general surgery, dental surgery, and anæsthetics. Facilities are now available for advice on postgraduate orthopædic training through the Postgraduate Orthopædic Committee which has its headquarters at the college.

At **St. Mark's Hospital**, City Road, London, E.C.1, surgeons wishing to specialise in proctology may attend a six-month course, and postgraduate students working for higher degrees may come for 1–4 weeks' whole-time study. Intensive courses, each lasting two weeks, are held in conjunction with the Fellowship of Postgraduate Medicine three or four times a year.

The **London School of Hygiene and Medicine** offers a course for the certificate in public health, beginning in October and academic year (the preliminary part, from December, being followed by the certificate). During the second part of the students may elect to make a special study of: trial health; (2) statistics; (3) hospital (4) tropical hygiene. The elective course in health is recognised in part as qualifying for the tion for the diploma in industrial health; and tunities are given for visits to factories and industrial establishments.

The school also provides courses for the bacteriology and in tropical medicine and a short course in medical statistics.

The course in bacteriology, starting in October, academic year and is intended to give advanced to graduates in medicine or veterinary science who follow a career in bacteriology.

Two courses in tropical medicine and hygiene are year, beginning in March and October and months.

The course in medical statistics occupies two days for three months, beginning in April and also in applications are sufficient.

The **Royal Institute of Public Healt Hygiene** offers courses for the certificate in health, starting approximately at the April and October; and for the diploma, February and August. The institute also course for the diploma in industrial health; the for part 1 is the same as that for the certificate in health, while that for part 2 begins in July. Further information may be had secretary, 28, Portland Place, London, W.1.

At the **Tavistock Clinic** the psychotherapy adults and children as outpatients, based on concepts, which has characterised the clinic's in the past, is being developed, and particular is being given to group psychotherapy. In therapeutic work the clinic and the associated Institute of Human Relations are studying preventive psychiatry. These include mothers' groups, selection techniques, and techniques for ing interpersonal relations in industry and psychological and sociological procedures. In the *department* the following activities will begin autumn: (1) a course in outpatient special reference to group methods for a limited of participants of senior registrar status; and (2) lecture-discussion courses in psychopathology and psychology for trainee psychiatrists. In the *guidance department* systematic training is at available for a limited number of psychiatric educational psychologists, child psychotherapists, psychiatric social workers. Both departments clinic have in addition: (*a*) a course for general tioners, once a week for ten weeks, likely to be regular feature; (*b*) case conferences open to a number of senior professional workers on request; (*c*) open case conferences for a limited number of workers. Further information may be had from training secretary, 2, Beaumont Street, W.1.

There are a limited number of opportunities professional training at the **Tavistock Institu Human Relations**. A programme of open discussions will be announced later. The activities of the institute centre on the psychological social aspects of medical, industrial, and problems. Further information may be obtained the secretary.

The **Institute of Psycho-Analysis**, 96, Place, London, W.1, provides training in theory and technique. The course is part-time and about four years. It includes a personal analysis, dance at lectures and seminars (held in the and clinical work done under supervision. required to obtain general psychiatric experience at clinics and hospitals, since the institute does not set all aspects of psychiatry. Completion of the o the satisfaction of the training committee the student for election as an associate member ritish Psycho-Analytical Society. In addition to n course designed for those intending to specialise, tute gives briefer courses from time to time on the ion of the principles of psycho-analysis to medical s. These are advertised in the medical press.

NORTH LONDON POSTGRADUATE MEDICAL INSTI- olds courses in advanced medicine, advanced and obstetrics and gynæcology; and instruction in pathology, anæsthetics, and radiodiagnosis. instruction is given at Bearsted Memorial l, Chase Farm Hospital, North Eastern Hos- orth Middlesex Hospital, and the Prince of General Hospital. During the coming academic here will be eight-week courses in advanced e suitable for those taking the M.R.C.P. examina- ght-week courses in advanced surgery suitable for aking the F.R.C.S. examination, and two-week for those taking the D.OBST. R.C.O.G. examination. r information can be obtained on application to n, Dr. J. Browning Alexander, the Prince of General Hospital. London, N.15.

FELLOWSHIP OF POSTGRADUATE MEDICINE, which office at 1. Wimpole Street, London, W.1, provides information on postgraduate work, and arranges of instruction as follows:

eekend courses, occupying the whole of a Saturday d Sunday. These are given in various hospitals in h subjects as infectious diseases, geriatrics, the rheu- tic diseases, ear, nose, and throat diseases, and clinical gery.

ourses specially suitable for, though not restricted to, ndidates for the D.A., D.C.H., D.OBST. R.C.O.G., M.R.C.P., d F.R.C.S. (primary and final). These include general edicine, neurology, general surgery, proctology, mid- fery, children's diseases, anæsthetics and anatomy, ysiology, bacteriology, pharmacology, and pathology. me are full-time courses, lasting 1–2 weeks. Others e spread over longer periods, taking place either in the ornings, afternoons, late afternoons, or evenings; ey are intended particularly for postgraduates not e for full-time study.

In Scotland

EDINBURGH POST-GRADUATE BOARD FOR MEDICINE, enting the university and the Royal Colleges of cians and Surgeons of Edinburgh, arranges pro- mes of graduate studies. The board offers courses ernal medicine, general surgery, medical sciences, dvanced obstetrics and gynæcology, and refresher es for general practitioners.

o courses in internal medicine, lasting 12 weeks, are starting in April and October of each year. These s comprise lectures, lecture-demonstrations, clinical ing, and clinical pathological demonstrations; they itable for graduates wishing to specialise in medicine o require a refresher course in the current outlook ternal medicine.

o courses in general surgery are held each year. ing in March and October. These courses are of eeks' duration; they include lectures on surgical ology and selected surgical subjects, as well as al demonstrations and ward visits for the class nall groups. In addition to the Edinburgh Royal mary, other general and special hospitals in the city erate in the provision of clinical teaching facilities.

comprehensive course in the medical sciences of omy, physiology, and pathology is held in the summer; hours of instruction are given in this course, 100 of h are devoted to practical work; and in connexion it a series of twelve open lectures are given by ing authorities in their various specialties.

he course in midwifery and gynæcology is constructed arily for those who already have considerable erience in this specialty and are preparing for the .C.O.G.

eneral-practitioners' courses have been completely ganised, with the teaching either at the bedside or by means of lecture-demonstrations. Emphasis is laid on recent advances in treatment, and free discussion, as well as constructive criticism by members of the course, is encouraged.

Open postgraduate lectures of wide interest are organised in conjunction with the courses in surgery and medicine. An increasing number of overseas graduates are attending these courses and it is the intention of the board to provide a hall of residence as soon as possible. Courses are often booked up several months in advance, so those intending to apply should do so at an early date. Applicants should write, giving particulars of their medical qualifications and postgraduate experience, to the Director of Postgraduate Studies, Surgeons' Hall, Edinburgh, 8.

GLASGOW UNIVERSITY offers full-time intensive postgraduate courses in medicine and surgery twice a year. The courses run concurrently, are each of eight weeks' duration, and begin in mid-April and mid-October. These courses consist of clinical meetings, pathological demonstrations, and lectures; they are primarily designed for candidates training for the higher qualifications in medicine and surgery. Courses in pædiatrics, ophthalmology, dermatology, and other specialties are organised when the demand arises, and are advertised from time to time in the medical journals. Recognised training in diagnostic and therapeutic radiology is also available.

For general practitioners refresher courses of a fortnight's duration are held four times a year; they consist mainly of clinical demonstrations, but include also a few lectures on modern therapy. All inquiries should be addressed to the Director of Postgraduate Medical Education, The University, Glasgow, W.2.

SOME FURTHER POSTGRADUATE COURSES *

Anæsthesia

Courses in anæsthesia are held at Bristol and Liverpool, and in dental anæsthesia at Glasgow.

Bacteriology

The London School of Hygiene and Tropical Medicine and Manchester University run courses for the diploma in bacteriology.

Child Health

Courses in child health are held at Bristol, Glasgow, and Liverpool.

Industrial Health

Courses for the diploma in industrial health are held by the Society of Apothecaries of London, the Royal Institute of Public Health and Hygiene, and Edinburgh, Glasgow, and Manchester universities. Manchester University holds a refresher course for industrial medical officers.

At Roffey Park Rehabilitation Centre residential courses lasting one week are held for doctors and others. The syllabus is divided broadly under two headings: (1) maintenance of fitness at work; and (2) rehabilitation and resettlement. Classes are modelled on the lines of the open discussion group. Inquiries should be addressed to the secretary, Training Department, Roffey Park, Horsham, Sussex.

Medical Statistics

Courses in medical statistics are held at the London School of Hygiene and Tropical Medicine, and in statistics (for a university diploma) at Manchester.

Medicine

Among the universities providing courses in medicine are Liverpool (with a course taken by those studying for the M.D. and M.R.C.P.) and Sheffield.

Obstetrics and Gynæcology

A part-time course in obstetrics and gynæcology is offered by Liverpool University, and a course for the diploma in gynæcology and obstetrics by Trinity College, Dublin.

---

* The lists given in this section are not exhaustive.

because of previous experience, do not wish to take the comprehensive two-year course will be able to attend limited series of lectures and clinical instruction. There are facilities for original investigations under supervision in the clinical departments and in the psychological, neuro-anatomical, electrophysiological, and biochemical departments.

The *Institute of Urology* is associated with St. Peter's and St. Paul's Hospitals, Henrietta Street, W.C.2. Three courses of fourteen weeks' duration are held annually, commencing in January, April, and September. An intensive two-week course suitable for students taking higher examinations is held in September and March. Limited numbers of clinical assistants are appointed in January and July each year. Two courses in venereology, each lasting four months, are held annually, commencing in April and September.

The *Institute of Dental Surgery* is associated with the Eastman Dental Clinic. The object of the institute is to train dental practitioners in the special branches of preventive and therapeutic dentistry, both for children and adults, by means of clinical experience, lectures, demonstrations, and research. Opportunities for limited numbers of students are available in orthodontics, conservative dentistry, periodontia, and preventive dentistry, the courses varying from four to twelve months in duration.

It is essential for prospective students to make their arrangements well in advance. Those sponsored by their universities, governments, or other official bodies receive first consideration in the allotment of vacancies. Established specialists from overseas, here for a relatively short time, who wish to see something of the practice of this country, are always welcome; they are regarded as visiting colleagues, and the experts in their specialties are always ready to receive them and let them accompany them in their work and teaching. In addition, refresher courses for general practitioners are arranged at non-teaching hospitals in London and the home counties. The federation has a central administrative office at 3, Gordon Square, London, W.C.1, to which inquiries should be directed. An information bureau of post-graduate activities in London and other university centres is maintained.

The ROYAL COLLEGE OF PHYSICIANS OF LONDON holds a series of advanced postgraduate lectures, including some on pathology, biochemistry, &c. The lecturers are drawn from the provinces as well as London. The audience is limited to 200. Details can be obtained from the Secretary of the College, Pall Mall East, London, S.W.1.

The ROYAL COLLEGE OF SURGEONS OF ENGLAND has arranged a number of lectures and demonstrations to be held at the college. In surgery two series, each of 24 lectures, will be given during October and April, and at the same time clinical conferences will be arranged at selected hospitals. In anæsthesia two series, each of 45 lectures, will be given in October and March; in addition courses extending over a period of from one to two years are being arranged. Between October and January, and also between March and May, there will be a series of 72 lectures and practical demonstrations in anatomy, applied physiology, and pathology. Lectures in oral, dental, and general surgery will be held in February–March; and lectures and practical demonstrations on the application of the basic sciences to dental surgery will be held in July and January–February. Lectures and courses are arranged during the year jointly with the Institute of Child Health, the Institute of Laryngology and Otology, and the Institute of Urology. Specialists are available for consultation on postgraduate training in general surgery, dental surgery, and anæsthetics. Facilities are now available for advice on postgraduate orthopædic training through the Postgraduate Orthopædic Committee which has its headquarters at the college.

At ST. MARK'S HOSPITAL, City Road, London, E.C.1, surgeons wishing to specialise in proctology may attend a six-month course, and postgraduate students working for higher degrees may come for 1–4 weeks' whole-time study. Intensive courses, each lasting two weeks, are held in conjunction with the Fellowship of Postgraduate Medicine three or four times a year.

The LONDON SCHOOL OF HYGIENE
MEDICINE offers a course for the certific
in public health, beginning in October
academic year (the preliminary part, f
December, being followed by the exam
certificate). During the second part
students may elect to make a special stud
trial health; (2) statistics; (3) hospital
(4) tropical hygiene. The elective cour
health is recognised in part as qualifying f
tion for the diploma in industrial healt
tunities are given for visits to facto
industrial establishments.

The school also provides courses for t
bacteriology and in tropical medicine and
a short course in medical statistics.

The course in bacteriology, starting in Oct
academic year and is intended to give adva
to graduates in medicine or veterinary science
follow a career in bacteriology.

Two courses in tropical medicine and hygien
year, beginning in March and October and
months.

The course in medical statistics occupies tw
for three months, beginning in April and also
applications are sufficient.

The ROYAL INSTITUTE OF PUBLIC
HYGIENE offers courses for the certificat
health, starting approximately at the
April and October; and for the diploma,
February and August. The institute also
course for the diploma in industrial health;
for part 1 is the same as that for the certific
health, while that for part 2 begins in F
July. Further information may be had
secretary, 28, Portland Place, London, W.1.

At the TAVISTOCK CLINIC the psychother
adults and children as outpatients, based on
concepts, which has characterised the clinic'
in the past, is being developed, and particula
is being given to group psychotherapy. In
therapeutic work the clinic and the associated
Institute of Human Relations are studying t
preventive psychiatry. These include mothers'
groups, selection techniques, and techniques f
ing interpersonal relations in industry an
psychological and sociological procedures. In
department the following activities will beg
autumn: (1) a course in outpatient psych
special reference to group methods for a limite
of participants of senior registrar status; and
lecture-discussion courses in psychopathology an
psychology for trainee psychiatrists. In t
guidance department systematic training is a
available for a limited number of psychiatric
educational psychologists, child psychotherap
psychiatric social workers. Both departments
clinic have in addition: (*a*) a course for genera
tioners, once a week for ten weeks, likely to b
regular feature; (*b*) case conferences open to a
number of senior professional workers on reques
(*c*) open case conferences for a limited number o
workers. Further information may be had fr
training secretary, 2, Beaumont Street, W.1.

There are a limited number of opportunit
professional training at the TAVISTOCK INSTIT
HUMAN RELATIONS. A programme of open lec
discussions will be announced later. The t
activities of the institute centre on the psycholog
social aspects of medical, industrial, and comm
problems. Further information may be obtained
the secretary.

The INSTITUTE OF PSYCHO-ANALYSIS, 96,
Place, London, W.1, provides training in psych
theory and technique. The course is part-time and
about four years. It includes a personal analysis,
dance at lectures and seminars (held in the
and clinical work done under supervision. Student
required to obtain general psychiatric experience at
clinics and hospitals, since the institute does not set

all aspects of psychiatry. Completion of the o the satisfaction of the training committee the student for election as an associate member ritish Psycho-Analytical Society. In addition to a course designed for those intending to specialise, tute gives briefer courses from time to time on the on of the principles of psycho-analysis to medical s. These are advertised in the medical press.

ORTH LONDON POSTGRADUATE MEDICAL INSTI- olds courses in advanced medicine, advanced and obstetrics and gynæcology; and instruction in pathology, anæsthetics, and radiodiagnosis. instruction is given at Bearsted Memorial l, Chase Farm Hospital, North Eastern Hos- orth Middlesex Hospital, and the Prince of General Hospital. During the coming academic here will be eight-week courses in advanced e suitable for those taking the M.R.C.P. examina- ht-week courses in advanced surgery suitable for aking the F.R.C.S. examination, and two-week for those taking the D.OBST. R.C.O.G. examination. information can be obtained on application to n, Dr. J. Browning Alexander, the Prince of General Hospital. London, N.15.

FELLOWSHIP OF POSTGRADUATE MEDICINE, which office at 1, Wimpole Street, London, W.1, provides information on postgraduate work, and arranges of instruction as follows:

eekend courses, occupying the whole of a Saturday l Sunday. These are given in various hospitals in h subjects as infectious diseases, geriatrics, the rheu- tic diseases, ear, nose, and throat diseases, and clinical gery.

urses specially suitable for, though not restricted to, ndidates for the D.A., D.C.H., D.OBST. R.C.O.G., M.R.C.P., d F.R.C.S. (primary and final). These include general dicine, neurology, general surgery, proctology, mid- fery, children's diseases, anæsthetics and anatomy, ysiology, bacteriology, pharmacology, and pathology. me are full-time courses, lasting 1–2 weeks. Others e spread over longer periods, taking place either in the ornings, afternoons, late afternoons, or evenings; ey are intended particularly for postgraduates not e for full-time study.

In Scotland

EDINBURGH POST-GRADUATE BOARD FOR MEDICINE, enting the university and the Royal Colleges of cians and Surgeons of Edinburgh, arranges pro- nes of graduate studies. The board offers courses ernal medicine, general surgery, medical sciences, dvanced obstetrics and gynæcology, and refresher es for general practitioners.

o courses in internal medicine, lasting 12 weeks, are starting in April and October of each year. These s comprise lectures, lecture-demonstrations, clinical ing, and clinical pathological demonstrations; they itable for graduates wishing to specialise in medicine o require a refresher course in the current outlook ternal medicine.

o courses in general surgery are held each year, ng in March and October. These courses are of eeks' duration; they include lectures on surgical ology and selected surgical subjects, as well as al demonstrations and ward visits for the class nall groups. In addition to the Edinburgh Royal mary, other general and special hospitals in the city erate in the provision of clinical teaching facilities.

comprehensive course in the medical sciences of l pathology is held in the summer; are given in this course, 100 of n are devoted to practical work; and in connexion it a series of twelve open lectures are given by ing authorities in their various specialties.

he course in midwifery and gynæcology is constructed narily for those who already have considerable erience in this specialty and are preparing for the .C.O.G.

eneral-practitioners' courses have been completely rganised, with the teaching either at the bedside or by means of lecture-demonstrations. Emphasis is laid on recent advances in treatment, and free discussion, as well as constructive criticism by members of the course, is encouraged.

Open postgraduate lectures of wide interest are organised in conjunction with the courses in surgery and medicine. An increasing number of overseas graduates are attending these courses and it is the intention of the board to provide a hall of residence as soon as possible. Courses are often booked up several months in advance, so those intending to apply should do so at an early date. Applicants should write, giving particulars of their medical qualifications and postgraduate experience, to the Director of Postgraduate Studies, Surgeons' Hall, Edinburgh, 8.

GLASGOW UNIVERSITY offers full-time intensive postgraduate courses in medicine and surgery twice a year. The courses run concurrently, are each of eight weeks' duration, and begin in mid-April and mid-October. These courses consist of clinical meetings, pathological demonstrations, and lectures; they are primarily designed for candidates training for the higher qualifications in medicine and surgery. Courses in pædiatrics, ophthalmology, dermatology, and other specialties are organised when the demand arises, and are advertised from time to time in the medical journals. Recognised training in diagnostic and therapeutic radiology is also available.

For general practitioners refresher courses of a fortnight's duration are held four times a year; they consist mainly of clinical demonstrations, but include also a few lectures on modern therapy. All inquiries should be addressed to the Director of Postgraduate Medical Education, The University, Glasgow, W.2

SOME FURTHER POSTGRADUATE COURSES *

Anæsthesia

Courses in anæsthesia are held at Bristol and Liverpool, and in dental anæsthesia at Glasgow.

Bacteriology

The London School of Hygiene and Tropical Medicine and Manchester University run courses for the diploma in bacteriology.

Child Health

Courses in child health are held at Bristol, Glasgow, and Liverpool.

Industrial Health

Courses for the diploma in industrial health are held by the Society of Apothecaries of London, the Royal Institute of Public Health and Hygiene, and Edinburgh, Glasgow, and Manchester universities. Manchester University holds a refresher course for industrial medical officers.

At Roffey Park Rehabilitation Centre residential courses lasting one week are held for doctors and others. The syllabus is divided broadly under two headings: (1) maintenance of fitness at work; and (2) rehabilitation and resettlement. Classes are modelled on the lines of the open discussion group. Inquiries should be addressed to the secretary, Training Department, Roffey Park, Horsham, Sussex.

Medical Statistics

Courses in medical statistics are held at the London School of Hygiene and Tropical Medicine, and in statistics (for a university diploma) at Manchester.

Medicine

Among the universities providing courses in medicine are Liverpool (with a course taken by those studying for the M.D. and M.R.C.P.) and Sheffield.

Obstetrics and Gynæcology

A part-time course in obstetrics and gynæcology is offered by Liverpool University, and a course for the diploma in gynæcology and obstetrics by Trinity College, Dublin.

* The lists given in this section are not exhaustive.

Health Services at Home

PUBLIC HEALTH

roduction of the National Health Service has effect on the duties of the medical officer of environmental hygiene. These responsibilities ved over the last hundred years from the basic ervices introduced with difficulty and by slow the instigation of the first M.O.H.s. Originally H. was closely concerned with the detailed of all this sanitary work, but the passage of led to the general acceptance of much that was secured with difficulty and spasmodically xpress personal intervention. Health depart- e now organised to allow the M.O.H. freedom ch detailed work which can be effectively per- y trained lay officers or even transferred to the other departments, as in water-supply and isposal. Naturally the extent of this devolution nsibility varies widely. Rural water-supplies ation remain a constant concern of the M.O.H. ervision of housing conditions, again mainly sanitary inspectors, is a health-department ility. All this work must remain under the ontrol of the M.O.H., and he must also supervise ty of water-supplies even though their production is concern. Though less concerned personally ailed sanitary work, he now supervises a far ld than his predecessor of a hundred years ago.

l of infectious diseases has always been one of the ncerns of the M.O.H. The old emphasis on isola- now been replaced by the provision of modern treatment but there remains the active home o. Bacteriologists have made great advances dentification of different strains within certain pathogenic species, and these new techniques, to epidemic control, have given the M.O.H. an ent of precision in much of his epidemiological The application of specific prophylactic measures various of the acute infections is now a major of health departments; and already the control of eases as diphtheria and enteric fever is in sight.

National Health Service Act has profoundly the work of the M.O.H.s of counties and county s—local health authorities as they now are. ve ceased to hold any responsibility for adminis- of hospitals, except that some individuals are s of hospital management committees. After cal Government Act of 1929 came into force, administration occupied the time of these in some sense at the expense of preventive e in which they have been specially trained. eless it will rest very largely with them to secure ordination of hospital and preventive services at nagement-committee level; indeed their influence point is crucial. No other medical men will be placed to survey the whole field of medical in an area. Regional hospital boards usually egular meetings of liaison committees of M.O.H.s, y on the M.O.H. of the local health authority to ine the urgency of social grounds for admission ents to hospital, especially maternity cases and onic sick. Local health authorities, under part 3 Act, provide clinic and other services for mothers reschool children, domiciliary midwifery, health g, home nursing, immunisation and vaccination, nces, care and aftercare, and domestic help; and have preliminary schemes for health centres. has been rapid growth of some of these services, ularly ambulances, home nursing, and domestic Their intrinsic importance is great, and their oution to the hard-pressed hospital service no less. .O.H. is the officer on whom the administration of services falls. Their complexity and the need for knowledge in day-to-day administration has led counties to devise schemes of divisional adminis- n which are of particular importance to the student se of their effect on the path of entry to the public- service, especially where divisional county posts ombined with the office of M.O.H. to one or more y districts.

mo the service will probably not, as
lier gh the clinical side but through
assistant administrative posts concerned with control of infectious diseases and organisation of clinic services. Thus there will be far less likelihood of medical officers who have taken postgraduate qualifications in public health devoting the rest of their professional lives to clinical work in a limited field. The very fact that those who undertake clinical preventive work will also be engaged in curative work will bring the administrative medical officer responsible for the organisation of clinic services into far closer contact with his professional colleagues. It is probable that experienced general practitioners will play an increasing part in the clinic services of local health authorities. For many years there will, of course, be whole-time officers engaged in clinic work, but it does seem likely that the public-health officer of the future will be usually concerned with organisation rather than with routine clinic duties. This redistribution of work coupled with the provision by local health authorities of health-centre buildings for general practice should help to produce an ever closer association between M.O.H. and general practitioner—a voluntary association arising from a knowledge of the help each can give the other.

The curriculum for the diploma in public health now provides a first part which is suitable for men engaged in tuberculosis or venereal-diseases work: a certificate is given to those who pass the examination for part 1 only. The course for part 2 provides for those who intend to take the diploma and enter the public service. Possession of a D.P.H. is necessary for anyone now seeking appointment as a medical officer of health.

INDUSTRIAL MEDICAL SERVICES

THE complexion of the industrial medical services is likely to be altered in the near future: and whether it is to assume a more roseate or more pallid hue will largely depend on the report of the committee which has been set up under the chairmanship of Judge Dale. The formation of this committee was announced by the Prime Minister on June 1, when he said that, to secure that the country's limited medical resources were used to the best advantage and with regard to economy, it was essential that these services should be organised so as to ensure that there was no duplication or misdirection of effort. The council of the British Medical Association on May 28 published a memorandum on a comprehensive occupational health service. It is likely that there will be as many schemes as there are interested bodies.

At present the main Government department supervising the health of industrial workers is the factory department of the Ministry of Labour and National Service. This department, which up to 1940 worked under the Home Office, dates from 1833 and administers the Factories Acts (1937 and 1948) with regulations on accident and sickness prevention, hours of work, amenities, and canteens. The staff numbers about 350, of whom 16 are doctors. All members of the department, whether lay or medical, take part in activities directed towards preventing illness and maintaining the health of the factory population. The medical inspectors are stationed in London, Birmingham, Sheffield, Liverpool, Bristol, Manchester, Glasgow, Leeds, and Wolverhampton; and from these centres they are able to deal with factory health and conditions in any part of the country. Under them 1750 general practitioners give part-time service as "appointed factory doctors" (previously called examining surgeons), examining all young entrants into industry and periodically all those engaged in specified dangerous processes.

A recent survey by the factory department of the medical services in different kinds of factories showed that of 243,769 factories in Britain 4499 have arrangements for medical services other than those supplied by the appointed factory doctors. General medical supervision is provided in 2525 factories, and supervision of first-aid and ambulance-room services in 2511, while in 2274 various groups of workers are given periodical medical examinations. There are schemes for looking after the workers on three trading estates—Slough, Bridgend, and Hillington. The Slough scheme covers 114 factories, of which 33 employ fewer than 26 workers: at Bridgend there are 39 factories, of which 15 employ fewer than 26 workers, while at Hillington 69 of 126 factories employ fewer than 26 workers. It has been an oft-repeated criticism of the industrial medical services that the workers at small factories are not catered for, and these three group-services might well form a model for a national service.

Whole-time service in factories is given by 53 doctors who are also appointed factory doctors and by 186 who are not. Of the total number of factories 4499 (1·85%) have medical arrangements other than the statutory examinations of young persons, the percentage increasing with the sizes of the factories. These figures perhaps give a false picture of the position if the close watch kept by the factory department on conditions in all factories is not kept in mind.

Apart from the factory department, other Government departments deal with various aspects of the industrial medical services. For instance, the Post Office, which employs more workers than any other department, has had a medical service since 1855; and since it deals with engineering and manual workers in addition to office staffs, it is partly an industrial medical service. The Ministry of Fuel and Power has a mines medical service, described below, and the National Coal Board also has a staff of medical officers. The Ministry of Supply medical service deals with the health of the workers in the Royal Ordnance factories and in the research stations such as Porton and Harwell. The Ministry of National Insurance has on its staff the former Silicosis and Asbestosis Medical Board, which deals with the diagnosis and certification for compensation of cases of silicosis and some other forms of pneumoconiosis. There are about 20 whole-time medical officers, who carry out these functions in addition to making pre-employment and periodical medical examinations of workers in certain industries liable to produce silicosis and asbestosis. A board consisting of three doctors was set up in Manchester in 1941 to issue compensation certificates to cotton-workers who develop byssinosis.

In addition to investigations and research into industrial diseases conducted by medical inspectors of factories, mines medical officers, and works doctors much fundamental research into environmental conditions has been carried out by investigators of the Industrial Health Research Board of the Medical Research Council. Clinical and field studies made under the ægis of the council's Industrial Pulmonary Diseases Committee include inquiries into the pneumoconiosis of coalminers and the byssinosis of cotton-workers. The London Hospital department for research in industrial medicine was established by the council in 1943, and a few years later, in conjunction with the Ministry of Fuel and Power, a bureau for research into the pneumoconiosis of South Wales coalminers was set up at Cardiff. Other research units have been established at Birmingham and Porton to study various aspects of industrial problems. Research into industrial health matters is also being undertaken by the various university departments mentioned below.

University chairs devoted to industrial or occupational medicine have been set up at Manchester and Durham and readerships at Glasgow and Edinburgh. The chairs of social medicine at Oxford and Birmingham include industrial medicine within their terms of reference, and the University of Sheffield has recently appointed a professor of social and industrial medicine. Students are likely to hear more about industrial and social medicine in their undergraduate courses. Postgraduate courses are held in London, Birmingham, Sheffield, and Manchester. Diplomas in industrial health (D.I.H.) have been instituted by the Society of Apothecaries, the Conjoint Board of the Royal Colleges of Physicians and Surgeons, Edinburgh University, and the Faculty of Physicians and Surgeons of Glasgow. Full-time courses for the diploma are provided by the Society of Apothecaries of London, the Royal Institute of Public Health and Hygiene, and Manchester, Glasgow, and Edinburgh Universities.

The Association of Industrial Medical Officers was formed some years ago by doctors interested in industrial health and branches have been established in various parts of the country; the *British Journal of Industrial Medicine* is sponsored by the A.I.M.O. in conjunction with the British Medical Association.

MINES MEDICAL SERVIC

THE Mines Medical Service of the Ministry of
Power since its inception in 1943 has cons
chief mines medical officer and his deputy at
and a mines medical officer in each of the
coal-producing regions of the country. The
have been selected primarily on account
experience of and qualifications for mining
work; and by virtue of their special knowle
environmental factors in mines they act in an
and consultative capacity to the Minister of
Power and his administrative officers, H.M.
of mines, mine managements, other Government
ments, medical bodies, and others concerned.

The work of the mines medical officers is d
securing that the health of the mine-workers i
tained at the highest level, particularly in re
occupational factors. They are therefore co
supervision of medical arrangements (including
at mines themselves, and with ensuring that
treatment and rehabilitation are available fo
workers following injury or illness, and that th
are used to the best advantage. Where the p
a necessary service falls short of need, it is their
propose improvements. They are also concer
investigation and research into illnesses
commonly among miners.

During the war years, the Ministry of Fuel and
medical staff was necessarily concerned with
temporary work, such as the medical aspects of
ment and conservation of man-power. Certain
schemes, however, were put into effect,
among which is that whereby workmen who are
at the mines, where they are often not readily a
to a doctor, can have morphine administered to
specially selected certificated first-aid men empl
the mines. Long-term policies were also develop
some of these are now well established, such
arrangements for medical examination of all
to coalmining below 18 years of age and the
examination, including X ray, of all entrants,
of age, to the South Wales coalfield. Another
ment of significance is the provision at certain
medical-treatment centres staffed by State
nurses working under the direct supervision of

PRISONS AND BORSTAL INSTITUTIO

AT the larger prisons whole-time medical
appointed, and at the most important ones
medical officers are assisted by one or more
officers. Salaries are in accordance with the
Civil-Service scales, and appointments are
unfurnished quarters are provided at most prison
moderate rental. Preference is given to
practical experience of psychological medicine
all-round knowledge of general medicine and
Appointments are made by the Civil Service Comm
6, Burlington Gardens, London, W.1, to wh
inquiries should be addressed.

At the smaller prisons no whole-time medical
are employed; local practitioners are usually ap
as part-time officers. Further particulars of
appointments can be obtained from the Prison
missioners, Horseferry House, Dean Ryle Street,
S.W.1.

Services Abroad

COLONIAL MEDICAL SERVICE

cies in the Colonial Medical Service occur in all the Colonial Empire, the greatest number being al Africa and Malaya. Candidates must ordinarily h subjects holding medical qualifications regis- the United Kingdom and should have had at lve months' postgraduate experience in hospital ppointment. Candidates for the permanent nust be under 40 or 45 years of age, according ge of compulsory retirement in the territory to ey are appointed. In West Africa this is 50 years, ost other territories 55 years. Contract appoint- or short terms are available for candidates who ve the age-limits or who, while being within nits, do not wish to commit themselves to a career at the outset. Officers appointed to the nt service are normally required to take a course cal medicine and hygiene either before going or during their first leave.

al officers are usually appointed in the first for general duties, which require all-round and a balanced outlook upon both preventive ative medicine. Such duties often imply the of a district hospital and responsibility for the administration of a district, although many are employed on clinical duties in the large s. Some posts are concerned purely with public- work, and for these the possession of a D.P.H. al experience in preventive medicine is necessary. general field there are ample opportunities for investigation, and subsequent specialisation is ged. Opportunities are offered wherever possible cers to study for postgraduate qualifications in anch of medicine, surgery, or public health.

ge number of specialist appointments exist which mally filled from within the service by officers he necessary aptitude and qualifications. For ppointments a very high standard of professional nent is required. Senior administrative appoint- are also almost invariably filled by the promotion ing officers. The Colonial Medical Service is unified hout the Colonies and promotion takes place in ministrative or specialist branches either in the y where the officer is serving or on transfer to r. The scope for promotion is therefore con- ble. The total of the establishments of the various ment medical departments amounts to some uropean medical officers and an even greater r of officers appointed locally.

ers possessing qualifications or experience in ogy would be considered for appointment to the tory establishments. Workers in the laboratories out pathological and biochemical examinations inical, forensic, and public-health purposes. In ranch has been carried out a great deal of the ch work which has led to important advances in nowledge of tropical medicine and local health ms. There are a number of vacancies for women s, especially for those with special experience in rics, school health, child welfare, and nutrition, gh their employment is not necessarily confined se subjects.

urally in tropical and subtropical countries diseases ar to hot climates predominate in the general n of morbidity; but the whole gamut of patho- l conditions found in temperate climates occurs in opics, and doctors in the Colonial Medical Service xpected to keep abreast of the trend of modern al opinion in Britain.

late years progress in the control of tropical diseases been so rapid that Europeans can now live in ort and in hygienic surroundings in areas which lecades ago were notoriously unhealthy. There is however, a great deal to be done; and with the nsion of medical services to raise health standards colonies, the Colonial Medical Service offers special rtunities and ample scope for initiative and original [illegible] in clinical subjects, preventive medicine, [illegible] arch. Full particulars of terms and conditions of service may be obtained from the Director of Recruitment, Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1.

SOUTHERN RHODESIA MEDICAL SERVICE

THE government of Southern Rhodesia maintains a medical and public-health service with an establishment of 19 whole-time administrative, specialist, or public-health officers and government medical officers. The rates of pay for the whole-time officers are:

	Annual salary
Secretary for Health	£2130
Director of preventive services; director of curative services	£1900
Regional medical officer of health; 2 directors of laboratories; medical superintendent, leprosy hospital; medical superintendent, mental hospital..	£1595–£60 to £1775
Senior schools medical officer; 2 radiologists	£1420–£60 to £1540 –£55 to £1595–£60 to £1775
Nutrition officer; radiologist; pathologist; psychiatrist	£1420–£60 to £1540
Assistant medical superintendent, mental hospital	£1240–£60 to £1360
Schools medical officer (man); 2 schools medical officers (women)..	£1040–£36 to £1184

Government medical officers are graded as follows:

2 senior government medical officers ..	£1595–£60 to £1775
4 senior government medical officers ..	£1420–£60 to £1540
44 government medical officers	£710–£30 to £1070

In addition to the salary scales shown, there is a cost-of-living allowance varying from £167 to £213 a year on a sliding scale. Children's allowances are also paid.

Whole-time medical officers and the six senior government medical officers are not permitted private practice but are allowed consultant practice. Government medical officers, except those stationed at Salisbury, Bulawayo, Umtali, Gwelo, Gatooma, and Que Que are allowed private practice, the value of which varies from £100 per annum upwards, according to the station. The duties of government medical officers include supervision of the 16 government hospitals and 82 native clinics, and attendance on police, boarders in government schools, and prisoners. They also undertake medicolegal work and public-health duties. Leave may be granted at the rate of one-eighth of service, and may be taken in periods not exceeding 184 days at a time. Study leave may also be granted. After two years' service medical officers under the age of 45 can be appointed to the fixed establishment, and contribute to a pension scheme. The retiring age is 60. On appointment, government medical officers are usually stationed at Salisbury or Bulawayo, where they are paid an allowance of £200 per annum in compensation for not being allowed to undertake private practice. They are usually required to do relieving duties at various out-stations until appointment to a permanent post. Appointments in Great Britain to the service are made through the High Commissioner for Southern Rhodesia, Rhodesia House, 429, Strand, London, W.C.2, who will supply further details on request.

SUDAN MEDICAL SERVICE

SINCE 1947, in pursuance of its policy of building up the professional services from trained and qualified Sudanese, the Sudan government has suspended recruitment of British officials on pensionable terms. At present there are opportunities for appointment of British doctors on short-term contracts for up to six years: the contracts may be renewable. These will be general-service posts and will be open to men probably up to the age of 45. The salary will be a good deal higher than for the long-term contracts, and for a man with special qualifications, or above the age of 40, will be in the region of £E1300 a year. At the end of their six years' contract these officials will qualify for a gratuity equivalent to six months' pay. Candidates must pass a strict medical examination. Free passages by air or by sea are provided by the government on the official's appointment. As regards leave passages, there is a government air charter system whereby officials and their families are provided with free passages to the United Kingdom; but those not wishing to take advantage of this charter may be given a leave passage allowance. No income-tax is payable in the Sudan. There is, in addition to the basic salary, a cost-of-living allowance varying from £E190 to £E390 according to the number of dependants. An official's first term of service is usually about eighteen months, after which he qualifies for leave. If he travels by the air charter system he is entitled to 80 days in the United Kingdom; otherwise he is entitled to 85 days between departure from and return to the Sudan. Accommodation is not provided free, but rent is paid on all government quarters.

MEDICAL MISSIONARY SERVICE

CHRISTIAN medical men and women who wish to offer their services where the need is greatest will find opportunities in medical missionary work. There are university medical schools, central and rural hospitals, and many opportunities for public-health work and research. *Christian missions can claim to have given* China a modern medical profession. In India and Pakistan they have helped to maintain high ethical and professional standards, and have specialised in nursing education. In Africa and other primitive regions they have pioneered rural health services and the training of subordinate staff. All over the world the work is becoming integrated with the government services though still maintaining its identity. For undergraduate candidates for the service there are hostels in London and Edinburgh, and also various scholarships. At least eighteen months or two years of resident appointments is advised for all, and special diplomas or higher degrees for some. Special missionary training is also required by some societies. Service is for terms of from two to six years according to the country and climate; there are opportunities for postgraduate study during furloughs. Offers for life service are expected, but short terms are considered. Salary is on a missionary subsistence basis with allowances, free passages and quarters, and pension provision. There are schools for missionaries' children at home and in many of the fields. Applications from students or qualified men and women should be made either to the secretary of one of the denominational or interdenominational missionary societies, or through the local branch of the Student Christian Movement or the Intervarsity Fellowship, or to the Chairman, Medical Advisory Board of the Conference of British Missionary Societies, Edinburgh House, 2, Eaton Gate, London, S.W.1.

BRITISH MEDICAL STUDENTS' ASSOCIATION

THIS association was founded in 1942, and its membership includes the student body of most medical schools in Great Britain and Northern Ireland; the Irish Medical Students' Association is affiliated. It is a purely professional body whose sole object is to promote the interests of students, by providing a means of communication between those at different universities and with other professional organisations and Government departments.

The *British Medical Students' Journal* undertook a new rôle recently when the editorial board organised on behalf of the B.M.S.A. a conference of editors of medical student magazines. Similar conferences are to be held each year. The other publication of the B.M.S.A.—the diary—was introduced last autumn. It proved very popular and is being republished with a number of improvements.

The main contact between the association and Government departments during the past year has been with the Ministry of Education. In consultation with the Ministry's representatives the B.M.S.A. has been able to explain to students the position of those with further education and training grants.

The organisation of clinical conferences continues to be one of the most important aspects of the association's work. Four or five of these are now held every year in various parts of the country, when a hundred or so students from many different medical schools meet for several days of concentrated work and social activity. Visits are made not only to the important hospitals and medical centres in the district, but also to char industrial centres of medical interest.

Efforts on behalf of medical students from medical schools who desire to visit the hospita country, and vice versa, have been especially en The conference of deans has agreed to the exc foreign and British students for the summer provided the deans concerned give their testimonials; and the regional hospital boar been very generous in responding to a request th should open their wards to visiting foreign stu is hoped that thus some return may be made great hospitality shown to medical students fr country when they travel abroad. The B.M.S contact with most other national medical organisations, but is not connected with an national student organisation. Correspondence be addressed to the secretary of the association House, Tavistock Square, London, W.C.1.

EMPIRE MEDICAL ADVISORY BURE

THE British Medical Association has set up the Medical Advisory Bureau with a view to ma stay of overseas medical visitors to this co profitable and pleasant as possible, by welcom and providing a personal advisory service. Th which is at B.M.A. House, Tavistock Square, W.C.1, caters mainly for Dominion and Colonia men and women who are staying in this cou postgraduate education or other purposes. Inf is obtainable about postgraduate education an of study for higher qualifications; and inquire put in touch with the organisations and a providing postgraduate education. The vis wishes to see something of the latest medical w own specialty can be put in touch with the ap experts.

A register of suitable hotels and lodgings is m by the bureau, and every effort is made to hel to solve the problem of finding somewhere to social functions and in other ways doctors Dominions and Colonies are enabled to m other and prominent members of the professi country. General information about trave facilities, exhibitions, theatres, &c., may also The bureau can be of greatest service to the vi writes as long as possible in advance of arriv information on the following lines: projecte arrival, mode of travel, whether accompanied period of stay, objects of the visit, and in w assistance is desired. On arrival a letter of int from the local hon. secretary of the visitors association, although not essential, would be The medical director of the bureau is Dr. H. A. S to whom all communications should be address

THE MEDICAL WOMEN'S FEDERAT

ALL qualified medical women are eligible as of the Medical Women's Federation, which l local associations all over the country and in Ireland, as well as a large London associatio overseas association linking up members all world. The federation is non-political. It medical meetings for its members and pu quarterly journal reviewing subjects of specia to women doctors. These naturally cover a of social medicine, including maternity and chil women in industry, the care of children and and delinquent children, the management o schools and day-nurseries, *women in prisons,* c approved schools and remand homes, the il child, and many related subjects. Advances in and gynæcology, and psychological studies of w children are also naturally of special interest doctors; and recent work in these branches of is reviewed in the journal. From time to federation undertakes social studies and pub results. It is also able to protect the intere members by presenting arguments in any ca there has been discrimination against women The federation's headquarters are at Tavisto North, Tavistock Square, London, W.C.1.

In England Now

ng Commentary by Peripatetic Correspondents

summer of 1914 at a farm in the hills in mid- ree hours' journey from my hospital. I was a woman who had been in labour for over he diagnosis was twins. There was no window droom, the temperature was over 100°F, the a wick dipped in oil, and I had two charcoal for my instruments. My anæsthetist was a ter who had never heard of anæsthetics and help was a doddering old crone of 80-odd, deaf nd hope. I used forceps and delivered a head. round to replace my forceps in the steriliser urning back found that the head had retracted ppeared. I was a bit shaken but thought, easy, the other twin is across the shoulder and l as a spring and withdrawn the head." I there- ied the first head up, brought the second head d delivered. At this stage my anæsthetist, in to my shout of "Stop pouring you fool!" *nan was far under) stopped work and I took* ian's heel *on my* forehead and hit the wall ne. When we got straightened out I found the nead had gone back. Now, I am of Scotch on but I would willingly have given £5 to have teacher, Dr. Peter Horrocks, to take on. But s wishful thinking, and after decapitating both . at last delivered a Siamese twin joined all ne side.

take it that if you deliver two heads and both you have quite possibly to deal with Siamese I have not seen this symptom mentioned as an the diagnosis, and it may be useful to anyone vith this unusual condition. As a matter of , the woman recovered and had normal deliveries rds.

ing our years as students most of us developed e ideas on what we would *not* like done to ourselves. uncture, even in our unskilled hands, was no hardship. Abdominal paracentesis, the removal tches, and pneumothorax refills, with or without hesia, though momentarily painful, were soon over. terisation and urethral dilatation were procedures oposed not to incur in the near future. But the idea of having a needle slipped between our spinous sses into the deeper recesses of our back at once ed the usual cutaneous responses to unpleasant tions. In postgraduate life, we came to include hoscopy in the same category; not because it ys produced trauma but because we had seen gh examples in which it did. We had watched tient straddling a straight-backed chair while a eman forcibly conducted a frontal assault with a straight weapon; we had leant heavily on the lders of a frail old body, whose efforts to reject ube returned him to the ward labelled "uncoöpera- " and we did not forget the delightful county cillor, who, fairly early in the proceedings, rose from the table and, in bare feet and long shirt, padded out of the theatre, anathematising the profession.

But my turn came, and I was glad that the anæsthetist effectively ensured that my coöperation would not entirely depend on my control of my reflexes. Passivity was in fact only once strained after the initial spraying, swabbing, and intratracheal injection. That was when the operator looked towards the left upper lobe. There was no doubt about the mechanical advantage enjoyed by the hand pressing gently on a bronchoscope in position. The thoracic inlet or the angle of the jaw provides a fulcrum, and the range of movement produced in my somewhat ankylosed neck really surprised me. So, though my flesh no longer creeps at the mention of the bronchoscope, I propose visiting a manipulative colleague for a little intentional neck-wringing before again placing myself so completely at another's mercy.

* * *

Many—perhaps even most—practitioners nowadays rely mainly on commercial circulars for their information on new drugs and therapeutic procedures. These circulars are attractively produced and usually contain a clear summary of recent work on the preparation concerned; but, inevitably, many of them are biased. The proper time to learn to appraise published work is as a student, when there is easy access to teachers who will point out the fallacies. If this habit is not cultivated during student days, how much harder it will be to acquire it afterwards when in practice, with few advisers and less time to spare. Any student who has not acquainted himself with the following books and journals in his medical school library has inevitably missed the university bus: *The Tissues of the Body*, by W. E. Le Gros Clark; *Recent Advances in Pathology*, by G. Hadfield and L. R. Garrod; *Nature*; *Physiological Reviews*; and, of course, *The Lancet* and *B.M.J.* Some critics will say that this sort of reading is not necessary or even desirable for the future general practitioner. I cannot agree, for it is the only way to learn how to judge the evidence for oneself—and incidentally to realise how ephemeral is the greater part of modern therapeutics.

* * *

The Oriental candidate was leaving nothing to chance. He had appreciated that his examiners were simple-minded old gentlemen. "Anorexia," he wrote, "is the condition when patient complains of no hunger. The patient says that he or she is not feeling hungry and is not inclined to eat. His appetite is always nil. The commonest cause of anorexia is having had a big meal."

A boisterous (Occidental) colleague tackled the question with gusto. "I am glad," said he, "that an essay is requested and not the usual direction to discuss the subject. For this affords me the opportunity to recommend that the stomach should be treated with becoming respect, and I heartily commend as an object lesson the instructive conversations between Nat Gubbins and his gastric diverticulum." Another "essay" was at least commendable for its brevity and frankness together with its implied appeal *ad misericordiam*. "Anorexia means loss of appetite, and since I do not know the mechanism of appetite I cannot do justice to anorexia."

I often wonder if the examinee who ends his paper with "*no time for more*" really supposes that he will earn some sort of bonus. The truly dramatic touch is added by a half-completed sentence or even word, as if the pen had been wrenched from the grasp by an adamant invigilator. To me it is distastefully reminiscent of the "thanking you in anticipation" bluff. Examiners may be simple-minded old gentlemen but hardly as simp. . . .

* * *

During an "at home" at a famous medical school I was impressed by the interest visitors showed in the small collection of historical relics—they even preferred these to the monsters which have such a fascination for lay people. It occurred to me that all medical schools should have and take a pride in such a collection, recording its past, not just for parents and charming sisters to admire but also for the inspiration of its students in their more receptive moments.

In making a historical collection one is apt to forget that the present is the past of the future. So present-day common objects which will be interesting in years to come should be preserved at the same time, such as complete sets of class-cards or notebooks. Where there is a photographic department, this can contribute to keeping a complete record of the hospital and school; or the aid of enthusiastic amateur photographers could be sought. Everybody should lend a hand. What a record it would be, for instance, if we had a complete set of candid photographs of famous lecturers of the past in action. An occasional charge on school or club funds could bring in a shorthand-writer to make verbatim reports of lectures—not special addresses but ones taken at random, so that the future historian would see just what lectures to students were like. And might not some students who have the diary-writing urge (and capacity) keep a detailed day-to-day record to illustrate the everyday incidents and life of the place?

If a medical school feels it is too much trouble to preserve and display reminders of its past at least it should not consider it below its dignity to keep a scrapbook, seeing that the Royal College of Surgeons has done the same—and fascinating volumes they are, too, among all the other treasures of Lincoln's Inn Fields.

* * *

The undergraduates of this university have had a variety of schooling; of say twenty students, three or four have been to public schools, seven or eight to grammar schools, and the rest to secondary schools. At a discussion group the other day the subject raised was the best type of education to advise parents to seek for their sons. Now these men were fourth-year medical students and had had plenty of opportunity to compare themselves one with another. What surprised me was the vehemence with which they advocated a boarding-school education for boys, especially when an only child is concerned. The basis for their attitude seemed to be the necessity of boys being taught responsibility. William Temple put the matter crisply at the Arnold centenary celebrations: "If you are to develop in people a sense of public spirit, it can only be done by making them members of a community in which they have a real measure of responsibility, so that they know that the tradition of the community is entrusted to them." If we are to obtain the full benefits of an extended education, those who guide our schools should put this principle into practice. As boarding-schools are impracticable on a numerically large scale, it is up to our secondary-school headmasters to introduce the "run by the boys themselves" system to the greatest possible extent.

* * *

There was no necessity for the M.R.C.P. candidate to be preceded by a man playing the bagpipes to advertise the land of his birth. Apart from his accent, his contribution to our consultation consisted of non-committal phrases with qualifications to satisfy all possible contingencies.

"Is that a diastolic murmur one hears in this situation?" "Well, I wouldn'a say that it wasn'a."

"Do you think digitalis would do any good?" "Well, perhaps it might not do him any harm."

"Would it be advisable to have those bad teeth extracted?" "Well, it might not be a bad idea."

At the end he requested some information about the quality of his performance. We examiners are prepared to parry this inquiry with the conventional regret that the regulations prohibit any such premature revelation. But he was so curiously persistent that I hinted that his anxiety was excessive and that in due course he would hear officially if his further participation in the examination was required. "But that's just the point," he explained. "I am going back to Edinburgh tonight and I'd like to know if I ought to take a return ticket."

* * *

During the war years there were good reasons for appointing student house-officers: not only did they do some useful work, but, for a man who felt that he had been allowed to lead a normal life too long as a privileged person, the job offered a rational outlet for his desire to be doing something. Now that this overriding urgency is past, teachers in medical schools should look further ahead. In at least one provincial teaching hospital students are still encouraged to fill gaps in house-surgeon
appointments. Five years is all too short a time
the theoretical basis of medical practice, and a
has not learnt his theory well as a student will n
it later; whereas a man who has never perf
lumbar puncture or set-up an intravenous
student will certainly learn to do so during his
job, when he can always obtain advice or
from the R.M.O. or R.S.O. Our teachers must

I have been "reviewing the literature" again.
a job! It isn't only that the papers on one's
seem to be intentionally distributed over every
on earth but that so many go out of their way to
their message and obstruct the reader. This
kind of thing:

Pardoy's Disease

A. B. PARDOY

M.D. Heckmondwike

It is interesting to note that the literature
relatively rare and ætiologically obscure disease of
adults has tended to grow considerably since the
of hostilities (cf. Hitler, A. in *Mein Kampf*) in
(*Eisenhower and Churchill 1945*). *Interest* was s
by the publication of an unselected series of 3
Pearce (1946); and further cases have since
subject of investigation by Brewer (1946), Stewar
Gurney (1947), Davy (1947), Widdon (1947),
(1948), and Cobley et al. (1949).

Ætiology and Pathology.—Prior to the ap
these reports the ætiology of the lesion was sp
and following them authoritative opinion has
the view that it is unknown. It cannot be de
it has been suggested that the disease is due to

Notes and News

SOURCE OF CORTISONE (COMPOUND E)

nce Hench[1] and his colleagues at the Mayo Clinic 1 that rheumatoid arthritis dramatically improves ment with 17-hydroxy-11-dehydrocorticosterone d E, 'Cortisone') chemists have been trying to w methods of preparing the drug and searching er sources of raw material. The present source holic acid, obtained from ox-bile. The preparation, entails 36 chemical stages, all with a small yield, mething like 12,500 tons of beef cattle is required e enough bile to make sufficient cortisone to treat tic patient for a year. The scarcity of cortisone, being produced only at the rate of 200 g. a month erck Laboratories, at Rahway, New Jersey, may be y the fact that it now costs £1500 a week to treat nt.[2] Since the dose is 100 mg. daily. the present output is only sufficient for the prolonged treatment odd patients. Even so this would cost the almost ible figure of £400,000 a month. The need for ces of supply is thus readily understood.

me is a compound containing a cyclopentenophenan- ucleus, which is also present in vitamin D, the s of the adrenal cortex, the sex hormones, the bile e saponins, and the cardiac glycosides, such as Kendall, who isolated cortisone, obtained it from far back as 1929, Jacobs and Heidelberger,[3] of the ler Institute for Medical Research, isolated a cardiac , sarmentocymarin. from the seeds of a species of thus, *Strophanthus sarmentosus*. From this by is they obtained a sarmentogenin, although for many ere was considerable confusion over the identity species that yielded this substance. More recently in of Basle, who spent nine months in Africa collecting s of strophanthus, has definitely identified *S. sar-* s as the source of sarmentogenin. The importance ompound is that it is more nearly related to cortisone ical structure than is desoxycholic acid. American s have now converted sarmentogenin into cortisone ocess involving 20 stages.[4] This is still a formidable is, but a great improvement on the 36 stages necessary conversion of desoxycholic acid into cortisone. Unless horter synthesis is devised the seeds of *S. sarmentosus* the raw material from which cortisone will be obtained future. Supplies of the plant, which is a vine that on the trunks of trees in Liberia and other parts of should be practically unlimited. It can be propagated eds and cuttings and if necessary could be cultivated rge scale in Africa. It might even be grown in other ial regions, though when plants are grown out of their habitat the yield of drug obtained from them may fall. re already under way to try to cultivate *S. sarmen-* American possessions with a suitable climate. It is nial but takes about five years to bear seed, so until tion is well established cortisone is still likely to be The possibility that other species of strophanthus yield sarmentogenin should not be overlooked. One is certain; unless some new and novel source of ne, or an allied substance, is discovered, arthritic ts in this country will have to wait a little time for upplies of the drug.

enocorticotrophic hormone (A.C.T.H.), which seems to ndirectly, much the same effect as cortisone, is reported[5] [illegible] at the rate of 60 pounds a year by the Armour [illegible] Chicago from hogs' pituitary glands. This [illegible] d treat 2000–4000 patients, but the present t is being allotted entirely to American hospitals for l trial.

TWO NEW JOURNALS

introducing the first quarterly number of the *Journal Faculty of Radiologists* the editor (Dr. Peter Kerley, ed by Dr. F. Campbell Golding and Dr. Frank Ellis) ns that it will mainly be devoted to clinical radiology ill aim to establish a closer link between members of aculty and radiological colleagues at home and abroad.

The *Annals of the Institute of Laryngology and Otology*, of which the first issue has appeared, is designed to record the work done in the institute itself and at the associated Royal National Throat, Nose, and Ear Hospital. Contributions are invited from past and present members of the institute.

ROUND AND ABOUT STEPNEY

Winifred Stamp's biography[1] of Dr. Harry Roberts tells much of his lively mind, humanity, wit, and incorruptible determination to go his own way (though he always managed to do it without harm to others): and it also tells, unintentionally, much of Winifred Stamp. Those who knew the people in this short arresting book recall gratefully her gift of telling a story—used splendidly here—the generosity of her mind. the ease of her friendship, and her superlative cooking. Dr. Roberts was as different from ordinary people as his house was different from ordinary houses; and though it has not been possible to crowd into 163 pages more than an outline of his odd and impressive character, the picture is done so deftly that his friends will say again and again, "There he is: that was Harry"; while those who never met him will find themselves waiting pleasurably for the next characteristic bit of behaviour, the next bold stroke on behalf of some oppressed group or other. His life as a doctor in Stepney. his long career as a journalist, his considerable political influence, his green thumb, and the group of friends who shared his adventures all find their place in this book: but its chief charm lies in the sense of comedy which carried these friends through the extraordinary situations to which Harry's versatility continually introduced them.

University of Cambridge

On Aug. 20 a special congregation was held to award honorary degrees to members of the first International Congress of Biochemistry now meeting in Cambridge. The degree of D.SC. was conferred on Lord Addison who was presented as the father and patron of medical studies, on Prof. C. F. Cori of the Washington University school of medicine. on Sir Charles Harington, F.R.S., director of the National Institute for Medical Research, on Dr. Kaj Linderstrom-Lang. of the Carlsberg Laboratory, Copenhagen, on Prof. Arne Tiselius. of the Royal University of Uppsala, and on Dr. Jacques Tréfouel, director of the Pasteur Institute.

Edinburgh Post-Graduate Board for Medicine

On Monday, Aug. 29, at 4.30 P.M., in the anatomy theatre of Edinburgh University, Dr. C. H. Andrewes, F.R.S., will speak on Influenza in Perspective.

Royal Institute of Public Health and Hygiene

Dr. René Sand, professor of social medicine in the University of Brussels, will deliver the Bengué lecture on World Trends in the Teaching of Social Medicine and Public Health. He is to speak at the Institute, 28. Portland Place, London, W.1, on Thursday. Sept. 15, at 3 P.M.

Royal Free Hospital

A clinic on rehabilitation will be held by Dr. Howard Rusk of New York at the hospital, Gray's Inn Road, London, W.C.1, on Wednesday, Sept. 14, at 2.30 P.M. Those who wish to attend should notify the medical rehabilitation unit at the hospital.

Medical Research Council

The council have made the following travelling awards for the academic year 1949–50:

Rockefeller Travelling Fellowships in Medicine

Mr. W. J. Atkinson, Mackenzie Mackinnon research fellow (Royal College of Surgeons), National Hospital, Queen Square, London.

Dr. Ruth E. M. Bowden, lecturer in anatomy, Royal Free Hospital school of medicine, London.

Dr. R. Daley, first assistant, cardiology department, St. Thomas's Hospital, London.

Dr. J. Dawson, lecturer in biochemistry, University of Leeds.

Dr. C. E. Lumsden, senior lecturer in pathology, University of Aberdeen.

Dr. J. S. Robson, assistant, departments of medicine and clinical biochemistry, University of Edinburgh.

Dorothy Temple Cross Research Travelling Fellowships in Tuberculosis

Dr. A. J. Robertson, medical registrar, Royal Infirmary. Liverpool.

Mr. J. D. Wade, surgical officer, Welsh National Memorial Association (Sully Chest Centre).

Travell [illegible] *Arrangement with the Centre* [illegible] *in France*

Dr. I [illegible] rsity of Bristol.

Miss [illegible] research unit, psychological [illegible]

[1] Doctor Himself. London: Hamish Hamilton. 1949. Pp. 163. 10s. 6d.

South-East Metropolitan Regional Tuberculosis Society

A meeting of this society will be held at B.M.A. House, Tavistock Square, London,, W.C.1, on Saturday, Sept. 10 at 10.30 A.M. when Mr. R. C. Brock will speak on the Secondary Effects of Tuberculous Mediastinal Lymphadenitis with special reference to Disease of the Middle Lobe.

Vitamin B$_{12}$

A solution of crystalline vitamin B$_{12}$ is now being marketed under the name 'Anacobin.' Supplies are restricted; and the manufacturers, the British Drug Houses Ltd., urge that it should be used only for patients who are intolerant of liver extracts or who have a personal or family history of allergy.

War Pensions Review Tribunals

The Ministry of Pensions announces that applications for review of cases by the special review tribunals will not be accepted after Nov. 30. These tribunals were set up in 1946 to enable claimants whose appeals had previously been disallowed to have their cases reconsidered in the light of certain High Court judgments which had affected pension law.

Course on Rheumatism

A weekend course on the chronic rheumatic diseases, with lectures, ward rounds, and practical demonstrations, will be held at the rheumatism unit, St. Stephen's Hospital, Fulham Road, London, S.W.10, on Oct. 1 and 2. The course is being opened by Sir Ernest Rock Carling, and the following will take part: Dr. Francis Bach, Dr. Grace Batten, Dr. Philip Ellman, Mr. A. Timbrell Fisher, Dr. Jackson Richmond, Dr. David Shaw, Dr. A. G. Signy, Dr. C. C. Worster-Drought.

Chartered Society of Physiotherapy

The annual congress of this society will be held at St. Pancras Town Hall, Euston Road, London, N.W.1, from Sept. 14 to 18. Dr. J. A. Charles, deputy chief medical officer of the Ministry of Health, will give the opening lecture on Progress Reports from Home and Abroad, and Sir Harry Platt the founders' lecture on the Causation and Prevention of Deformity. Lord Horder will be in the chair at the dinner which will take place at the Savoy Hotel on Saturday, the 17th, when Mr. Aneurin Bevan will be the principal guest. Further particulars may be had from the secretary of the society, Tavistock House North, Tavistock Square, W.C.1.

Refresher Courses for General Practitioners

Financial help may now be had by general practitioners attending special short courses offered by universities and medical schools and consisting of 3 half-day sessions at the weekend or during the week. Under this new arrangement, which supplements those announced last year,[1] a doctor may take in one year a maximum of seven courses of 3 sessions, or any combination of such courses with 11-session courses which does not exceed 22 sessions. The course fees are paid direct by the Ministry; and travelling expenses and subsistence allowance may be reclaimed by those qualifying for grant.

Registration with General Practitioners

Application forms (E.C.1) for registration with a general medical practitioner under the National Health Service are to be withdrawn from post offices and public libraries. They will still be obtainable from executive councils, from doctors' surgeries, and (on the registration of a birth) from the registrar of births. This step is being taken, says the *Ministry of Health*, because of evidence "that the readiness with which the form is at present available encourages some persons to use that form when it ought not to be used—e.g., for a change of doctor (when the medical card should be used). When this happens, there is a potential risk of inflation in the executive council's registers if the form E.C.1 is not completed fully and accurately."

The 1949 edition of the *Register of Special Therapists* is obtainable gratis by doctors on application to the Registrar of the Board of Registration of Medical Auxiliaries, B.M.A. House, Tavistock Square, London, W.C.1.

INSULIN THERAPY

SUCCESSES AND PROBLEMS *

R. D. Lawrence

M.A., M.D. Aberd., F.R.C.P.

TO KING'S COLLEGE HOSPITAL, LONDON, IN CHARGE OF THE DIABETIC DEPARTMENT

ns certain from all Banting's lines of research was essentially interested in the discovery of therapies to relieve the suffering and diseases nd: immediately interested in practical humani- forts more than in pure researches on physio- ecrets such as glycogenolysis or the twitchings r's gastrocnemius. As a clinician he could, of ave been the most successful in the world and ave had the richest and most interesting of s. Not only had he and Best discovered insulin boratory, but they were the first to apply insulin n treatment. Clinical facilities seem to have been for him in Toronto, but clinical teams went ısly to work on the thera- se of insulin, with Campbell tcher at the General Hos- d Mackay, Hipwell, and Dr. christ—himself a diabetic e Christie Street Hospital her centres. Banting was involved, but not in clinical at these centres. In his work he was again in a position, because his early and interests had been inantly surgical; and he dly qualified for full medical in spite of demands of cs from everywhere.

so ultimately laboratory h claimed the rest of g's working life. But his drive and stimulus arose ne suffering sick.

Dr. Fred Banting after a clinical round in 1922.

SUCCESSES

marvellous effect of insulin in ng vigorous health to diabetics no scientific proof but only stimony of severe diabetics ed by its use. This was movingly shown by a d meeting of the Diabetic Association held in n in 1946 to honour the memory of Banting. out Banting," said their diabetic chairman, "this g could have been only a gathering of ghosts ning their fate."

ay the use of insulin is steadily increasing in all ies: in Great Britain, for example, between 1942 48 it rose as shown in the graph. This increase has doubts about the future adequacy of supplies. No if the needs for insulin of countless untreated ics in India and China were suddenly imposed on t sources of production these needs could not be but by the time a realistic and rational demand from such backward countries I should think the eases of countless Chinese pigs and even sacred cattle will be forthcoming. It is true that, even he problem of less wasteful collection of pancreas etter generalised methods of extraction should be ntly in mind; but I do not see that diabetics fear that in another 10–20 years their insulin ements will not be met. Man's scientific ingenuity lve any such problem when it arises.

Meanwhile laboratory work—more exact and less diversified than that of the clinician—has clearly established that many enzyme systems take part in the total use of carbohydrate: it is almost certain that insulin acts primarily by stimulating the enzyme hexokinase to change unutilisable glucose into a phosphate compound, which becomes available as fuel. And other experiments have shown that insulin deals with an inflow of carbohydrate food not only by increasing immediate combustion in the diabetic but also by storing an excess—partly as glycogen but mainly as fat. And we know more exactly the processes by which, in the diabetic without insulin, these stores flow out into the blood and urine as sugar and ketones. But the clinician has long felt or known that insulin makes carbohydrate available and the details of how it acts have not yet made therapy more easy or efficient.

To the clinician the major question at present is how to use the various types of insulin as physiologically as possible to suit the life of diabetic man. It was in some similar purpose and not in abstractions that Banting found his stimulus. To keep a laboratory diabetic animal alive by insulin is relatively easy. But the good clinician must strive to direct a life of normal efficiency and happiness to suit his patients' habits, desires, and temperament; must aim at normal longevity; must be aware of the complications that other illnesses and environmental changes produce to change the usual rhythm of insulin action and the diabetic life. It is no business of his to interfere too much, to change or distort the life of a diabetic in his charge, except to prohibit really harmful habits and factors. With this in mind, let us turn to some clinical problems concerning the action of insulin, in which the humanitarian attitude must never be forgotten. And may I add that we claim no ultimate knowledge of living processes, and that our clinical therapies, however successful, are based on many obscurities of cause and effect which cry for elucidation. May I be excused too for confining myself here mainly to my own often unpublished experiences.

INSULIN TREATMENT PHYSIOLOGICALLY IMPERFECT

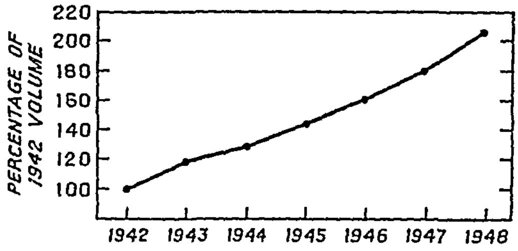
One main problem in insulin treatment is that no type of injected insulin can act physiologically to produce a rhythm of carbohydrate metabolism similar to the normal. In non-diabetic people the blood-sugar level is raised for 1–2 hours after carbohydrate food and then rapidly returns to normal, remaining there without any hypoglycæmia. We do not know whether this is due to a nicely adjusted extra secretion of insulin to meet the amount of absorbed carbohydrate—a reasonable concept—or to an inherent liver rhythm of glycogenesis; and we shall not know this, nor the answer to other important problems, until an accurate method of estimating blood-insulin is discovered.

All types of injected insulin given, as they should be, to suit normal habits as nearly as possible, are very imperfect. The long-established treatment with a morning and an evening dose of soluble insulin has given, and gives, wonderful clinical results; but the moment insulin action is exhausted in a severe diabetic hyperglycæmia and ketosis comes surging back

---

Banting memorial lecture of the Diabetic Association ered on July 22 at King's College Hospital, London.

in 1–3 hours—quicker indeed than the next dose of insulin acts in their reduction. In severe cases we can make a nearer approach to normality by giving two doses, morning and evening, of partially delayed insulins —the original protamine insulin without zinc ('Retard' of Hagedorn) or globin zinc insulin, which I think identical in time action. Since 1937 it has been our practice at King's College Hospital for severe diabetes to use a pre-breakfast mixed dose of protamine zinc insulin (P.Z.I.) and soluble insulin, and the results, while reasonable in the control of hyperglycæmia, have certainly been good as regards nutrition. For milder cases, one adequate dose a day of any type of insulin, but preferably a delayed form, may be very satisfactory—probably because the patients still produce some endogenous insulin. But let me emphasise that no-one who does not know the different actions of various insulins, in strength and timing, can ever use insulin with full efficiency, whether for physiological control or for the strength and comfort of his patients.



Rise in the use of insulin in Great Britain.

VARIED INSULIN NEEDS AND ABSOLUTE DIABETES

I shall now discuss the different insulin requirements, both variable and constant, of different types of diabetics. From this discussion I exclude the middle-aged obese "diabetic" free of ketosis, whom I have described in many papers (Lawrence 1941, 1946) as suffering from, I think, a fundamentally different type of sugar disturbance, to be treated by reducing diet and not with insulin. What follows refers to the severe wasting case, with ketosis as well as glycosuria, who must have insulin for health and even for bare survival.

In my experience the same acute need for insulin is seen in the young (under 35) and in real old age (over 70), when again a newly developed diabetes is usually severely ketotic. (What a contrast to the usual mild obese type of 40–65 years!) In treatment of these cases increasing doses of insulin are given in the first few days until the blood-sugar becomes normal at the period of maximal insulin action, some hyperglycæmia and glycosuria being present at other times. The dose must then be reduced from perhaps 40–80 units a day (10–20 in a 4-year-old) to much less, some 20–30 units in an adult. After this the insulin requirements may remain level for a long time; but in another group of patients they continue to decrease, and very occasionally insulin may be stopped. In these new treated cases we may hypothecate that the function of the beta cells of the pancreas —or at least their production of insulin—was only half destroyed, and that the reduction of hyperglycæmia by exogenous insulin allowed recovery, very extensive if never complete. There is no doubt from animal experiments that hyperglycæmia progressively destroys islet function, and all my clinical experience bears this out. There are other types of mild diabetes, made temporarily severe by sepsis or other complicating endocrine factors, in which the patient may come off insulin and indeed seem almost cured of the disease. Unfortunately we cannot follow even in animals the islet changes that might correspond to these changing clinical phases.

However we may theorise, the vast improvement often seen, particularly in young children, leads to great difficulties and psychological stress for parent

It has been very obvious again how a low f total diet, and particularly carbohydrate equires very little insulin, but a higher level of n soon requires much more insulin with a vast ment in energy and weight.

was particularly clear in experiments on myself have never published. In 1923 it seemed possible e might cure diabetes or recreate pancreatic n by keeping the blood-sugar normal, or below for a long time. For six months, therefore, I a very low diet (16 g. carbohydrate, 70 g. protein, fat), with all the insulin I could stand, only s a day (8 and 7). After six months of this weary e I ate more, and my requirements rose to s; I became if not fighting, at least playing, fit. ears later I put myself back on the previous low st 10 lb. in ten days and returned justifiably to lier dose of 15 units a day. From this one should ber that the dose of injected insulin needed varies lute diabetes with the intake of food and the body- Allen abundantly proved this in pre-insulin by his undernutrition treatment of canine and diabetics. Insulin requirements in absolute es are largely a function of weight and food and a vast reduction of insulin is sometimes seen wasting conditions of terminal carcinomatosis or of anorexia nervosa.

EXTREME INSULIN RESISTANCE

us now turn to one of the greatest obscurities in treatment, the patient who requires enormous of insulin, 500 units or more a day. I am not ng to those cases in which complications—usually ons—require temporarily a large increase in insulin ck ketosis and prevent coma. What I have in are long periods of vast unexplained insulin with a return later to average requirements.

quantitative needs of such patients are as clear he average case. If they require 1000 units per or control, 1200 units will produce hypoglycæmia 00 permit a relapse with ketosis. And so they e quantitatively like an average case, but the dosage multiplied 10–30 times. The most ehensive and important paper on this condition Smelo (1948) who reviews 54 published cases.

re is no type, age, or nutritional state in which this ance especially develops. The first patient I studied lad of 25 who needed 400 units a day from 1924 27, and then gradually returned to some 60 units, ich he has remained ever since. From 1944 to 1947 5 other such cases (unpublished), but I have seen in the last twelve months, so the condition is very I have not seen an uncomplicated case which was ant at the beginning of insulin administration. In xperience they respond to average amounts of n at first, do well clinically, and then develop the n-resistant state mostly in about three months. of this are loss of weight, thirst, and much glyco- and ketosis on the previous effective dose. The n must be boldly raised merely to prevent coma. me cases, raising the insulin from 50 to, say, 100–150 a day will control the diabetes. A complicating r may be found: but the real resistant cases I am concerned with do not respond so easily and require hundreds of units a day even to save life, and inly to restore health. At this stage inpatient ment is essential, and the use of the highly concen- d insulin solution (320 units per ml.), kindly ared by Messrs. Boots Pure Drug Co., has been most able in reducing the uncomfortably large bulk of the l preparations. I have compared the action of 640 s soluble insulin given as 2 ml. of the special preparation with that of 640 units given as 8 ml. (i.e., 80 units per ml.) and have been unable to observe any difference in speed, strength, or duration of action. When insulin is given intravenously these cases show an equal resistance. I should mention that P.Z.I. is too weak in circulation to be of any use, though I admit I have not experimented with a depot injection of thousands of units.

The plan of treatment followed is essentially the same as in non-resistant cases: insulin dosage is pressed rapidly until ketosis first disappears, glycosuria is reduced to a minimum, and the blood-sugar is controlled so that there is no hypoglycæmia at the time of maximal insulin action—a tricky process. I do not pretend to know when a dose of 600 units produces its maximum action. We usually find that the patient needs the biggest dose before breakfast (e.g., about 600 units), much less before supper (200–400 units), and sometimes we must add a small (!) dose of 100 units at lunch. When a controlling dose is reached, be it 600 or 1600 units a day, a balance between food and insulin is reached. An increase of 200 units produces typical hypoglycæmia, an equal reduction a relapse of sugar and ketones. But always in our cases a point has been reached when less and less insulin controls the situation and ultimately the dose necessary for control returns to an average one. This reducing phase is full of danger of hypoglycæmia unless there is close and regular supervision.

Can we give any explanation of this rare and strange phenomenon? Neither our experience, nor any published work I know, gives any satisfactory reply. In the 5 cases I have seen, all complicating septic or endocrine conditions were excluded, as far as possible; but most cases have shown a rise in erythrocyte-sedimentation rate during this resistant state, which disappeared when it ended. Severe diabetes does not affect the sedimentation-rate, and this finding may have significance. None of these patients has shown any local or general allergic manifestations to insulin. A few have been examined, by the rabbit technique, for resistant components in the plasma, with negative results. It has been suggested that in these resistant phases the patient develops antibodies, reagins, call them what you will, which react with injected circulating insulin and make it almost ineffective. Lowell (1944) has published the most suggestive—but far from convincing—article on this thesis. Like so many problems of medical science, it stands unsolved at present, a fascinating challenge to speculation and sifting experiment. And we need never fear that by solving one problem we shall solve all those that make scientific medicine so fascinating. For, when we have found an answer to one immediate problem, it always proves to be only penultimate, leading to another. We reach another stepping-stone in a river too wide to see the further bank. This is what makes medical science a stimulating and vivifying, though sometimes an overtiring, pursuit.

CARDIOVASCULAR AND OTHER COMPLICATIONS

The diabetic state gives rise to very interesting organic changes in many systems of the body, and all the results noted are, at least to me, ætiologically unsolved problems. The vascular effects are the most important and devastating, and on these I shall concentrate in a moment. But before this I would note the interesting changes in the eye focus, the acute cataract, and the sometimes temporary lens opacities that occur with diabetic phases of dehydration and rehydration, apart from the retinopathy which all too often develops after years. Evanescent or prolonged peripheral neuritis, and its obscure relation to the vitamin-B complex, is another problem.

There is no doubt that, as the years go on, diabetes produces widespread associated degenerations, primarily in the vascular system. We knew that these occurred in the elderly mild cases, but the long survival of the young effected by insulin shows in many the same disastrous pattern of complications. Twenty years ago I taught the students that many elderly diabetics developed a triad of retinopathy, albuminuria (with or without hypertension), and gangrene, commonly all present together. And now to watch this same picture, though without gangrene, develop in more and more young patients is a tragedy and a challenge.

It seems probable that the same type of vascular *degeneration must be induced in most of the organs*, whether it be first noted clinically as retinal hæmorrhages, slight albuminuria, or mild hypertension. One often sees in the eyes some punctate retinal aneurysms (see Ballantyne, 1948, for full description and histology) for five to ten years before other complications appear, the rest of the cardiovascular systems remaining strictly normal. These hæmorrhages may come and go, and I have seen them—and sometimes even exudates and massive cholesterol deposits—completely disappear, never to recur. Ophthalmologists are apt to disbelieve, because they do not see such cases unless they watch patients for years at a diabetic clinic. I have a large group of them, mainly at 55–70 years of age. Another unfortunate group, mostly between 30 and 40, before any arteriosclerosis or hypertension is present, develop a quickly progressive retinopathy, with large hæmorrhages into the vitreous from bursting irregular veins and new preretinal vessels, and may be nearly blind within two years (retinitis proliferans). Another group, mostly those with long-standing diabetes from childhood or later, after a few retinal hæmorrhages over a year or two, or even before any hæmorrhages, begin to develop slight hypertension, often before albuminuria; and I look with grave suspicion at a blood-pressure rising from 110/70 to 125/90 as one commonly sees in these young adults. And in another few years we find their renal and hypertensive elements progressing rapidly until the full syndrome of renal failure or hypertensive disasters is complete. The universality of intercapillary nephrosclerosis (Kimmelstiel Wilson syndrome) is now recognised. The early retinal diabetic picture is obscured by added renal features, with arteriosclerotic changes, œdema of retina, choked disc, and woolly exudates.

Similar observations have been reported from studious clinics in every country, and the subject was discussed at the American Diabetic Association in 1948. Dr. Priscilla White (1948) reported 92% affected in 220 patients originally under 16 who had suffered for 20 or more years from diabetes developing in their childhood, and Dr. Dolger (1948) reaffirmed his finding of 100% affected of all ages after 25 years' duration. Our experience at King's College Hospital is bad but not so devastating, and I know 7 patients, myself included (29 years), who are free of such vascular stigmata. And I know of one case of 39 years' duration completely free of all vascular complications. So while one case shows lesions at an early stage—$4\frac{1}{2}$ years is the earliest clearly dated case in my experience—others may escape for another 30 years, without any fundamental difference in their diabetic state. The innately different quality of vascular resistance must play a part in diabetic as well as other types of vascular degeneration. *One sees a similar state* of blood-vessels at 40 and 85.

Ricketts (1948) made a very balanced assessment of possible causes in this vascular situation and found no causative agent beyond the prolonged diabetic condition.

As it is not obvious how hyperglycæmia per se would cause vascular changes, other thinkers look for a common causal factor for both the diabetes and the vascular degeneration. I myself suggested four years ago a common hidden basis, perhaps pituitary, producing vascular degeneration and diabetes; for I had never seen vascular changes in the pure and prim islet and pancreatic destruction, found in h tosis and in chronic and relapsing pancreatitis. this idea has been shaken by two describing retinopathy in relapsing pancreati 1947) and in hæmochromatosis (personally me from Australia by Dr. Stawell). These seem to me to dispose of the above hypothesis me back to the diabetic state, probably hype as the primary and direct cause. This leads t question. Does clinical experience show that controlled cases develop vascular complicatio and more often than the better controlled?

I think they do. The first complicated cases I saw were in the most wildly unc revolting from excessive parental anxiety or the exuberance of adolescent freedom—and reasonably well whether their average bloo 300–500 or 100–300 mg. per 100 ml. The Bos has assessed poor control in their childre incidence of coma and finds more complicatio cases. But one sees retinitis equally common long-standing cases in middle-aged people have such exuberant hyperglycæmia, but wh sugar runs from 200 to 250 ml. for years, o before diabetes leads to troublesome sympton disturbance from retinitis is quite often their sign of diabetes; indeed, in 1945 at King Hospital 15% of the newly diagnosed cases al retinopathy. And so I think that it is years glycæmia that we find associated with vascula and I do not know whether a high or mode *makes much difference.*

Unfortunately we do not know whether cæmia in diabetes would prevent these com though that seems to me likely from the sma of very mild cases I have seen for years witl near-normal glycæmia and no vascular com But the majority of the diabetics I treat normoglycæmic for most of their hours, and unlikely that other people's patients are diffe mild patient controlled and nearly aglycosur has usually a near-normal blood-sugar ran about 130 to 200 mg. per 100 ml. The average i on 30–50 units a day is strictly orthoglycæm a few hours, at the height of insulin activit certain other times has blood-sugar of abou This might be prevented by giving small doses four or five times in 24 hours, but it cannot be by any possible treatment with only one or two a day without perpetual risk of hateful hypo And so in my cases, and I think all others, hyperglycæmia are constantly present. An confidently claims to maintain a physiologica blood-sugar in the average insulin case has, no wide or accurate experience.

And is it, as 15–20 years go on, this hype which induces vascular change? Other cholesterol and lipoid *abnormalities, general* or vitamin deficiencies, protein and mineral seem almost ruled out. But we are left guessing how hyperglycæmia does harm. Could it do *mere physicochemical* effect of excess circulatin Or does a mildly defective nutritional sta endothelial degeneration? Is there some process peculiar to vascular normality whicl interferes with? The difficulty of the subject justify the formation and investigation of any which might bear on it.

Experimental work on animals, that illumina has so far been of little help in the problem o degeneration. Dragstedt (1945) reports undu sclerosis in depancreatised dogs, and Lukens a pillary glomerulosclerosis in a dog diabetic I do not think retinal lesions have been ls, perhaps they have not been seriously he long-term nature of such animal es them very difficult and tedious.

OTHER PROBLEMS

lems fascinate and puzzle me as a ention a few more worthy of study. continued insulin injections is different patients. Some show ge except a slight local fibrosis, Others develop huge fibro-fatty lumps, nen and children develop disfiguring areas phy in injected areas and sometimes in nearby ected parts. In a few individuals the insulin produces local allergic effects, and very rarely and generalised allergy.

eculiarities of diabetic *pregnancies* are being y studied at present, and it is held by the hool that imbalance of the hormonal picture of y is the cause of frequent maternal toxæmia leath of the progeny. Research is in progress centres, but the problem remains sub judice.

ocial problems arise for diabetics from the long thy life that Banting has given them, and in clinician is intimately concerned. Brief mention ade of a few. The question of their employment, erannuation, and life assurance—still often by pre-insulin prejudice—is gradually being their favour. Special Banting memorial ent homes and educational homes for difficult children have been established, initially by the drive of our unique Diabetic Association of nd the doctors concerned with it. A happy effort, which has also begotten today's memorial.

CONCLUSION

are the particular qualities of mind and spirit l to scientific discoveries such as Banting and What makes men devote themselves to such d pursuits which we must consider the quint- f human progress? Never direct financial gain: umanitarianism; partly ambition to make a d satisfy the power complex by success; but think, the need of the inquiring mind to explain wonder. This inquisitiveness, this search for ion, for a logical pattern of cause and effect is n human mental processes, from the puzzled of a child to the adult questionings of the and the philosopher. Banting always had the of scientific inquiry and imagination to a high quality difficult to define. It seems to consist ly in a *critical refusal* to accept current theories lanations; to look at known facts themselves in nd personal way; to notice contradictions and ncies in existing thought; to build in the tion a new explanation and then to work on this our and with an open mind, to prove or disprove hypothesis by controlled experiment. And the he hardest and requires faith, hard work, dour qualities, all of which the two discoverers of needed in the highest degree to bring Banting's fruition.

tain the open mind is a difficulty which leads tray in scientific work. It is all too easy to become n favour of our own hypothesis, the darling child magination; to invent experiments to prove our to neglect disappointing discrepancies that ict: and so, by neglecting facts, to give birth ror which may take ten years to expunge. It is to act like a lawyer pleading and proving his l not like a factual scientist who must be ready to imself disappointingly wrong.

I conclude by honouring the memory of Banting, whose example of sane imagination and vigorous determination should live in our lives today.

THE GUILLAIN-BARRÉ SYNDROME OR ACUTE INFECTIVE POLYNEURITIS

C. P. PETCH
M.D. Camb., M.R.C.P.
PHYSICIAN, ST. HELIER HOSPITAL

Guillain, Barré, and Strohl (1916) described a severe form of flaccid paralysis in two soldiers who had complained first of abnormal sensations in the feet, then of weakness of the legs which made walking difficult. Later the legs and then the arms became paralysed, with some involvement of the trunk and, in one case, of the neck. The cranial nerves, however, were not affected. There was no fever and no preceding illness. In spite of the apparent severity of the condition at its height, both soldiers completely recovered, leaving hospital after forty-one and thirty-three days. Examinations of the cerebrospinal fluid (C.S.F.) revealed normal pressures, normal cell-counts, and negative Wassermann reactions, but an increased concentration of protein, reaching 250 mg. per 100 ml. in one case and 85 mg. per 100 ml. in the other. No evidence of diphtheria was obtained from throat swabs, and there was none of alcoholism. These workers drew attention to six features that they regarded as important: motor impairment, abolition of tendon-reflexes with preservation of cutaneous ones, paræsthesiæ with only slight objective sensory change, pain on pressure over muscle masses, slight modification of the electrical reactions, and hyperalbuminosis of the C.S.F. without cellular reaction.

For this clinical picture the name of polyradiculoneuritis was proposed, since it was held that, though the symptoms were due to a polyneuritis, the alterations in the C.S.F. denoted an inflammation of the spinal nerve-roots in their intrathecal course. Polyneuritis of toxic origin was well known but was not thought to affect the C.S.F. Osler had described an "acute febrile polyneuritis" of unknown ætiology which presented a similar course, but a sharp fever (103°F) was a characteristic feature, whereas the French cases were afebrile. Since 1859 the name of Landry had been attached to a type of acute ascending flaccid paralysis which differed in being usually fatal. Polyradiculoneuritis therefore was offered as a new entity.

Some years earlier Laurens (1908) had collected from reports published between 1859 and 1905 eighteen cases which are of interest in this connexion, though many of the descriptions were written before the introduction of lumbar puncture. Laurens grouped them together because of the facial paralysis, which Guillain did not at first realise could occur in his polyradiculoneuritis, and in some cases the rest of the illness is briefly alluded to, but eleven of the eighteen are described in such detail as to leave no doubt that we are reading of what Guillain et al. (1916) called polyradiculoneuritis and other workers the Guillain-Barré syndrome. Other descriptions antedate that of Guillain et al., but Laurens's collection is the most striking.

Similar illnesses in Allied troops were subsequently noted. Holmes (1917) reported "about twelve" cases of symmetrical flaccid paralysis which he said "might be provisionally included under Sir William Osler's title of acute febrile polyneuritis." It seems that the pyrexia was not well marked, and he noted: "It has rarely been possible to observe the degree or type of fever at the onset." In the light of subsequent experience it seems unjustifiable to separate this group on the basis of fever alone. Case-records are not given, but the paralysis was often preceded some weeks earlier by a brief infective episode, such as an influenza-like attack or a sore throat. Hesitant micturition was noted, but catheterisation was never needed. Facial paralysis was usually present, dysphagia sometimes, and diplopia on three occasions. Two patients died of pneumonia, the rest recovering completely. Lumbar puncture, done in three cases, showed *no abnormality of cells or* other constituents, but the C.S.F.-protein is not stated and may not have been estimated. In the opinion of many workers these cases fall into the Guillain-Barré group. The name "acute febrile polyneuritis" did not persist.

Bradford et al. (1919) made a more elaborate study on British troops in France, summarising their findings in some thirty cases, which they stated were of the same type as Holmes's. There was the same symmetrical flaccid paralysis, with abolition of the tendon-reflexes and little objective sensory change. The facial nerves were involved seventeen times, the sixth once; dysphagia and palatal paralysis were rare. The proximal limb muscles were most affected, a point which in my own experience is significant. Fever does not seem to have been well marked. Four C.S.F. examinations were made and said to be normal, but again no C.S.F.-protein levels were given. Eight patients died, and from glycerinated emulsions of the spinal cords of three of these a similar disease was said to be produced in monkeys (*Macacus rhesus*) by subdural inoculation. These workers were thus led to propose a new name: "acute infective polyneuritis." The transmission experiments have been much criticised and have never been successfully repeated, but the name has persisted in British writings, where it must be regarded as synonymous with the Guillain-Barré syndrome.

The French did not admit the identity of the two conditions, holding their syndrome to be always benign, but this distinction could not be maintained. With increasing knowledge it was recognised that death could take place, especially from respiratory failure and if pneumonia developed. The supposedly characteristic C.S.F. findings turned up in other illnesses and were not always present in cases that were otherwise typical. Guillain for a long time resisted all modification of his original specification, and stated (Guillain 1936) that he preferred to exclude all fatal cases, all febrile ones, and all those with a C.S.F.-protein level less than 100 mg. per 100 ml. He accepted the frequency of seventh-nerve involvement, however, and his ten new case-records included examples of it. Later Guillain (1938) admitted the possibility of death in somewhat grudging terms. As regards the C.S.F. he agreed that the changes were never in themselves pathognomonic. Other contributors expressed similar views.

In America the term acute infective polyneuritis is less commonly used than the eponym Guillain-Barré syndrome. Many other names have been suggested.

CASE-RECORD

The following is a typical case of benign flaccid paralysis closely resembling that described by Guillain et al. (1916).

Case 1.—A married woman, aged 33, was admitted to hospital on June 13, 1947, unable to move her legs and with weakness of arms and face. Her illness had begun fourteen days previously, with tingling in her toes, first in the second and third toes of the left foot, then in the corresponding ones on the right. Seven days before admission she had
noted severe weakness in her legs, and since four
she had been unable to walk. At this stage then
tingling in her hands, and it had become difficult
the left side of her face. Shortly afterwards the
her face had become similarly affected, and wit
come a slight difficulty in swallowing and talki
had been no disturbance of sphincters, no anteced
and no sore throat.

On examination she was a well-developed wom

SUMMARY OF CASES

Age (yr.)	Extent of paralysis	Duration (days)	Result	C.S.F.-protein (mg. per 100 ml.)	Antecedent illness
33	All limbs, right and left face, and pharynx	108	Discharged walking	120 on 14th day; 450 on 28th day; 55 on 56th day	None
65	All limbs	125	,,	300 on 40th day; 500 on 60th day; 240 on 75th day; 160 on 99th day	,,
24	All limbs and left face	32	,,	> 100 on 12th day	,,
61	All limbs	76	,,	85 on 16th day	,,
33	All limbs, partially	54	,,	65 on 44th day	"Flu" a week before
48	Legs, and arms partially	47	,,	45 on 23rd day	One-day fever 3 weeks before
23	All limbs, and left face	125	,,	45 on 1st day	A cold 2 weeks before
13	All limbs, and right and left face	7	Died	140 on 5th day	A cold 3 weeks before

C.S.F. showed less than 5 cells per c.mm. in all specimens.

plantar reflexes flexor. The extensor plantar claimed by some to be present in the early d to afford evidence of implication of the upper urone, was not seen. Sphincters were unaffected, oss of voluntary muscle power and the enforced ιcy produced at times a little difficulty with on in the most acute phase. There was never en muscle weakness began, but in four cases s a history of a febrile illness a few weeks earlier. was normal in all respects except the C.S.F.- level, which was usually raised, sometimes the paralysis improved (cases 1 and 2). Recovery plete except in case 8, who developed convulsions spiratory function was still good, and died In 189 cases previously published 34 patients %), but this mortality is heavily weighted by re to recognise mild cases. Both sexes are affected, and the condition may develop at any remes of 2 and 78 years having been recorded. cases are the rule. I have not met the chronic polyneuritis described by some workers—e.g., (1940)—as the same condition, but it seems to erent disease.

PATHOLOGY

ontribution of morbid anatomy to the under- of this disease is slight. In those dying at ht of the paralysis—e.g., case 8—as well as those f unrelated intercurrent disease, the scanty ied lesions found post mortem give no clue to gin. Necropsies have been recorded by at least workers, from Laurens (1908) to Lewey (1945). al findings have been a polyneuritis with various of degeneration and, less commonly, inflamma- uch peripheral nerves as have been sectioned and pinal roots. The anterior-horn cells are the next ften mentioned site of change (Holmes 1917, d et al. 1919, De Jong 1940, Lewey 1945), and 1927) and De Jong (1940) found the lesion l to these cells and the homologous bulbar Degeneration of the long tracts is less common been supposed to be secondary (Roseman and 1941). Honeyman (1937) found no significant ality in a detailed examination of the nervous in four fatal cases. Case 8 of the present series, the investigation is not yet complete, promises little. It must be remembered that in a disease not often lethal post-mortem evidence may be misleading.

DIFFERENTIAL DIAGNOSIS

oliomyelitis

usion with acute anterior poliomyelitis causes the ifficulty, but usually the clinical pictures of the two diseases are distinct. Holmes (1917) listed some of the most helpful diagnostic features, and subsequent experience has added to them: Dagnelie (1938) gives a good summary. The differences are as follows:

(1) Patients with Guillain-Barré syndrome are afebrile and paralysed when first seen. If it is possible to relate the onset to an obvious fever, such fever has usually developed two or three weeks previously. Patients with poliomyelitis are usually febrile at the onset of the paralysis and for a few days beforehand.

(2) In the Guillain-Barré syndrome paralysis spreads at times very rapidly, but more often slowly, whereas the paralysis of poliomyelitis is classically maximal at the onset, though it may extend, especially to the medulla, in rare instances.

(3) In the Guillain-Barré syndrome the paralysis is symmetrical, or perhaps ascends a little higher on one side. The proximal muscles are most affected in the limbs, and the trunk tends to escape. In poliomyelitis a single limb, two on the same side, or odd groups of muscles are often affected, as is the trunk.

(4) Subjective sensory symptoms are greater and more persistent in the Guillain-Barré syndrome than in poliomyelitis, but genuine objective sensory loss is not a feature of either disease.

(5) Recovery, though sometimes slow, is complete in the Guillain-Barré syndrome, in contrast to the residual paralyses which are pathognomonic of poliomyelitis. There is not usually much muscle wasting in the Guillain-Barré syndrome.

(6) The C.S.F. in the Guillain-Barré syndrome usually shows at some period an increase in protein without any increase in cells. In poliomyelitis there is typically first an increase in cells and later in protein; but an increase in protein may be the only departure from normal. Jervis and Strasburger (1943) described a fatal case which never had more than seven cells per c.mm. but in which the C.S.F.-protein level rose to over 1200 mg. per 100 ml. in the fourth week. Necropsy showed lesions of poliomyelitis. These workers had made a "tentative diagnosis of Guillain-Barré syndrome" and emphasise the difficulty in diagnosis, but the onset with maximal paralysis and a temperature of 102°F should have aroused considerable doubt. Nicholson (1946) described three cases of poliomyelitis in which the C.S.F.-protein level was 74, 67, and 54 mg. per 100 ml. on the seventh, fourth, and fifth day of the disease respectively, cells being 5 or less per c.mm. Isolated C.S.F. findings should therefore be interpreted with reserve.

From Other Polyneuritis

Rarely do other forms of polyneuritis present difficulty. Diphtheritic polyneuritis is marked by the causal infection, and, though the C.S.F.-protein level is often raised without cells, the distribution of the paralysis is different. In faucial diphtheria, for example, the local paralysis of the palate and the paralysis of accommodation appear first, and may still be present at the onset of general weakness. Facial palsy is not common in diphtheria.

The remaining forms of polyneuritis are classically accompanied by a normal c.s.f., but Boudouresques (1938) has pointed out that any of the infective varieties may on rare occasions show an increase of c.s.f.-protein. He summarised the infective forms as mainly motor and acute, and the toxic types as mainly sensory and chronic. There are obvious exceptions to this rule, but where paralysis is due to a metallic or organic poison it does not show the rapid onset and steady recovery found in the Guillain-Barré syndrome. Lead paralysis begins in the extensors of the wrist and is said to be greatest here even in the very rare case in which it becomes generalised. Alcoholic polyneuritis and the allied types due to aneurine deficiency occur in special circumstances and again do not show the same march of events as the Guillain-Barré syndrome; the c.s.f. was normal in sixty-nine alcoholic cases out of seventy examined by van Bogaert et al. (1938) and in one personal observation of mine.

TREATMENT

There is no specific treatment for the Guillain-Barré syndrome, and the tendency to rapid improvement makes the assessment of remedies difficult. The most important point is that the paralysis may involve the respiratory muscles and render artificial respiration necessary. Hence a mechanical respirator or "iron lung" is at times useful.

Aneurine.—Since the discovery of the effect of aneurine deficiency in impairing peripheral nerve function scarcely a case of polyneuritis has escaped the administration of this substance, and most of those described here are no exception. It is hard to say how much it assists recovery, but it is harmless.

Physiotherapy.—The benefits of physiotherapy are obvious and easy to understand.

Neostigmine.—Reports from America emphasise the value of neostigmine, which was tried because of a presumed analogy with poliomyelitis, where it is said to diminish muscle spasm. Test (1946) described a dramatic improvement in a woman, aged 22, within a few hours of its administration in doses of 0·5 mg. four-hourly; but the patient stayed two months in hospital, which is a fairly usual time for a case not so treated. Shaffer (1946) described a similar improvement in a boy, aged 8 years, treated on the same lines. He includes a graph of the maximal range of passive movement in various joints before and after starting treatment with neostigmine, and the increase recorded is considerable. Before treatment, however, measurements seem to have been made once a day, in contrast to eighteen times a day after it was started; hence suggestion possibly played some part. This child also spent two months in hospital. I am not impressed by the part alleged to be played by muscle spasm in the Guillain-Barré syndrome, and my trial of neostigmine did not produce sufficient benefit to encourage me to continue it.

SUMMARY

The description of polyradiculoneuritis by Guillain, Barré, and Strohl in 1916, subsequently modified by Guillain in 1936, is identical with that of the acute infective polyneuritis of English workers and the polyneuritis with facial diplegia of Laurens and American workers.

Its clinical picture is strikingly characteristic, and its recognition rests on this. Its features are a symmetrical flaccid paralysis with abolition of the tendon-reflexes and with well-marked subjective sensory symptoms without much objective change. The patients are afebrile but may have had an antecedent

Facial paralysis is common, but affection of cranial nerves unusual.

Complete recovery is the rule, but rarely may die.

An increase in c.s.f.-protein is usual but not nomonic.

There are no specific pathological findings neuritis and degeneration of nerve-roots may with occasional changes in the cord.

The ætiology is unknown, and the unproved.

Differentiation from poliomyelitis is impo not difficult.

Treatment can only be symptomatic.

MEDICAL UNIT, UNIVERSITY COLLEGE HOSPITAL

The effect of pentamethonium iodide bistrimethylammonium di-iodide) in normal and tensive people has been discussed by Arnold and heim (1949). The presence in this country of Goetz enabled its action on the peripheral circul be studied with his digital plethysmograph. time available has allowed only eight persons to —two normal, two hypertensive, and four with vascular disease. The results obtained in these and the production of commercial preparations drug have prompted the present report.

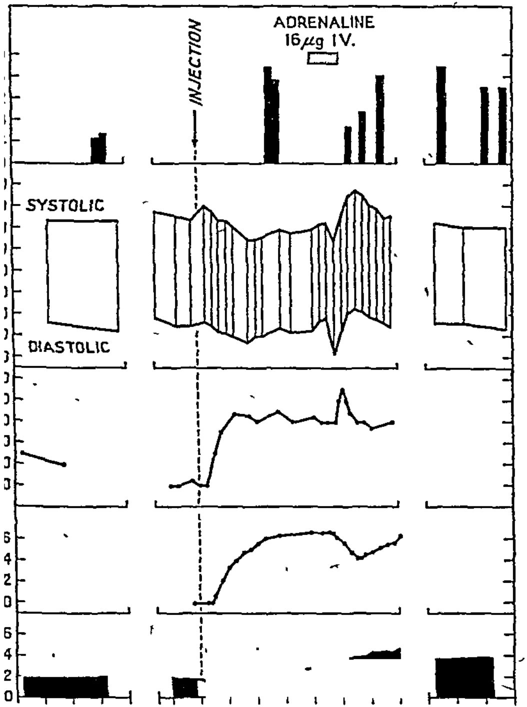
The value of continuous records of the pulse digital volume, and arterial inflow as measures peripheral blood-flow has been fully described (Goetz 1946, 1948, 1949). The digital plethysm permits the simultaneous recording of changes digits and also of respiration and skin te The pulse-rate can be obtained from the tracing some cases frequent blood-pressure readings were with a mercurial sphygmomanometer. The produced by pentamethonium iodide have been in the recumbent subject. The drug has been intravenously in doses of 40–50 mg. over a per 30 seconds.

RESULTS

The normal response to an intravenous dose of of pentamethonium iodide is shown in fig. 1, a graph prepared from the *continuous record.*

ume and digital volume begin to increase within) of the start of the injection, and full vaso- ı is reached within a few minutes. Vasodilatation or at least an hour and is accompanied by some in temperature. Immediately after the injection t-rate rises. In the normal recumbent person ittle or no fall in blood-pressure. Figs. 2 and 3 ngs from the records on which fig. 1 is based. e-volume in the big toes was doubled, rising from o ± 0·04 ml. (fig. 2). The increase in the rate al inflow, measured by the venous congestion tz 1946), is well shown in fig. 3.

nethonium iodide thus produces well-marked ıl vasodilatation. This can be counteracted with ıe. Adrenaline was given by intravenous drip rmal subject before and after injection of the . similar effect was observed on both occasions.) µg. of adrenaline was injected over a period minutes, eight minutes after the injection of



ıe effect of an intravenous injection of 50 mg. of pentametho- ıdide on the circulation of a normal man, and the effect of a ntravenous dose of adrenaline on the vasodilatation produced tamethonium iodide.

of pentamethonium iodide, there was a fall in nd digital volumes, a fall followed by a sharp rise l-pressure, and a further rise in pulse-rate (fig. 1). iew of the fall of blood-pressure it is known to e in patients with hypertension (Arnold and eim 1949), the effect of pentamethonium iodide peripheral circulation was studied in two such In the first the blood-pressure fell from 264/140 '104 mm. Hg after the injection of 50 mg. of the nd well-marked peripheral vasodilatation occurred . In the second patient there was a smaller fall d-pressure (from 260/154 to 214/136 mm. Hg) and ect on the peripheral circulation was much slighter. effect of pentamethonium iodide was studied in ıtients who had had either a cervical or a lumbar thectomy for peripheral vascular disease. In only se did the drug fail to produce some increase in volume, and this patient was examined when the vessels had not yet regained any vasomotor tone after the vasodilatation caused by lumbar sympathectomy.

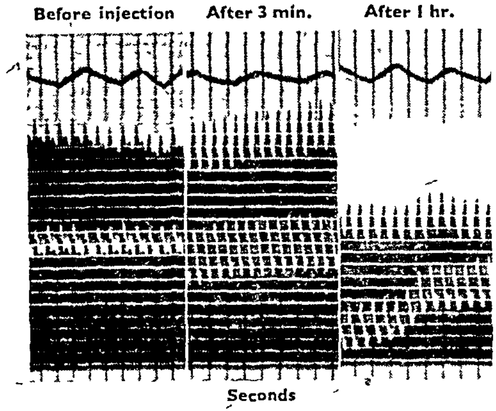


Fig. 2—Tracings obtained with the optical digital plethysmograph, showing the increase in pulse-volume following an intravenous injection of 50 mg. of pentamethonium iodide. The lower tracing records the pulse-volume of the left big toe, the middle tracing that of the right big toe, and the upper curve is a record of respiration.

That pentamethonium iodide may prove useful in the study of peripheral vascular disease is illustrated by the following case:

A woman, aged 43, was admitted to hospital with mild diabetes and intermittent claudication in the right calf. No pulsation could be felt in the right dorsalis pedis artery, but pulsation was readily palpable in the left dorsalis pedis and in both posterior tibial arteries. The flush of a reactive hyperæmia test reached the base of the left big toe in 4 seconds but took some 14 seconds on the right side.

The patient was given 50 mg. of pentamethonium iodide intravenously. Half an hour after the injection the pulse-volume had risen from ± 0·001 to ± 0·010 ml. in the right big toe and from ± 0·002 to ± 0·015 ml. in the left. During this time the skin temperature on the dorsum of the right foot had risen only 1·2°C, while that on the left rose 2·4°C. In the big toe the pulse-volume normally reaches at least 0·02 ml. in full vasodilatation (Goetz 1946). It was clear, therefore, that either the pentamethonium iodide had not achieved full vasomotor release or that arterial disease was present in both legs; but the change following the injection suggested that lumbar sympathectomy would improve the circulation in the right leg.

This operation was performed and the patient was investigated again eleven days later. At this time the right foot was warmer than the left. The pulse-volume, at rest, in the right toe (± 0·013 ml.) compared favourably with that obtained preoperatively after injection of pentamethonium iodide (± 0·010 ml.), while that in the left (± 0·002 ml.) was unaltered. After the postoperative injection of 50 mg. of pentamethonium iodide, the pulse-volume on the right side showed no material change, while that on the left rose

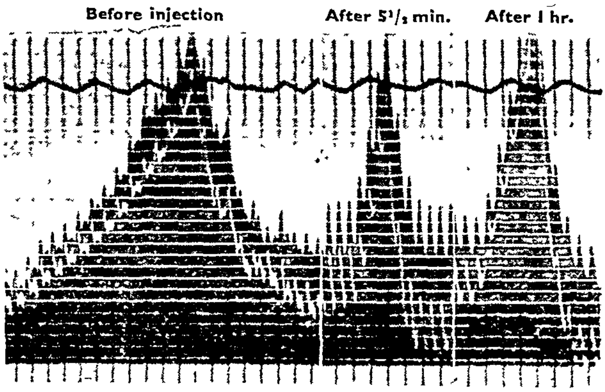

Fig. 3—Tracings similar to those in fig. 2, showing the increase in digital volume of the big toes during venous *congestion tests* before and after intravenous injection of 50 mg. of pentamethonium iodide in a normal man. The sharper rise in digital volume after the injection indicates an increased blood-flow.

to ± 0·012 ml. (fig. 5). Immersion of the hand in ice-cold water led to no change in the right but a considerable decrease in the volume of the left pulse. This suggested that 50 mg. of pentamethonium iodide had not blocked all vasoconstrictor impulses, but the injection of a further 25 mg. did not lead to a further increase in the left pulse-volume.

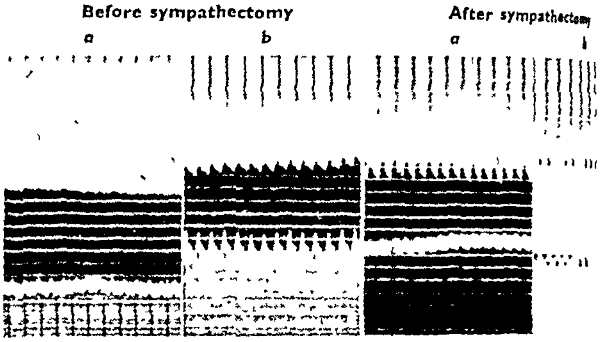

Fig. 5—The effect of pentamethonium iodide 50 mg., before and after lumbar sympathectomy, on pulse-volume in the right and left le of a woman, aged 43, with intermittent claudication in the right before injection; *b*, after injection. The upper tracing is from the the lower from the left big toe.

DISCUSSION

From a study of the effect of pentamethonium iodide in animals Paton and Zaimis (1949) concluded that it paralysed the transmission of impulses through the autonomic ganglia, having an action similar to that of tetraethylammonium salts. Arnold and Rosenheim (1949) found that the drug produced a fall of blood-pressure in hypertensive patients. This effect was, again, similar to that of tetraethylammonium chloride but lasted longer and was accompanied by fewer subjective sensations. This protracted action was also shown by the development of postural hypotension in a normal person more than an hour after injection.

Tetraethylammonium salts have been used in the investigation and treatment of peripheral vascular disease (Berry et al. 1946), but their value has been questioned (Boyd et al. 1948) because, with skin temperature and skin resistance as an index of vasodilatation, the results compared unfavourably with those following sympathetic block. It appeared possible that the protracted action of pentamethonium iodide would make it more useful than tetraethylammonium chloride in the investigation of peripheral vascular disease.

The effect of pentamethonium iodide on the peripheral circulation was therefore studied with the optical digital plethysmograph. In normal people peripheral vasodilatation has been demonstrated. This begins within a minute of intravenous injection, reaches its maximum within 3 or 4 minutes, and persists for a considerable time, being still present after an hour in one p The degree of vasodilatation, as judged by pleth graphy, could not be appreciated by recording the temperature, which responded rather poorly. confirms the contention put forward by Goetz (1949) that skin-temperature readings are unsatis in assessing peripheral blood-flow, and that es of arterial blood-flow in terms of skin tempera practically impossible.

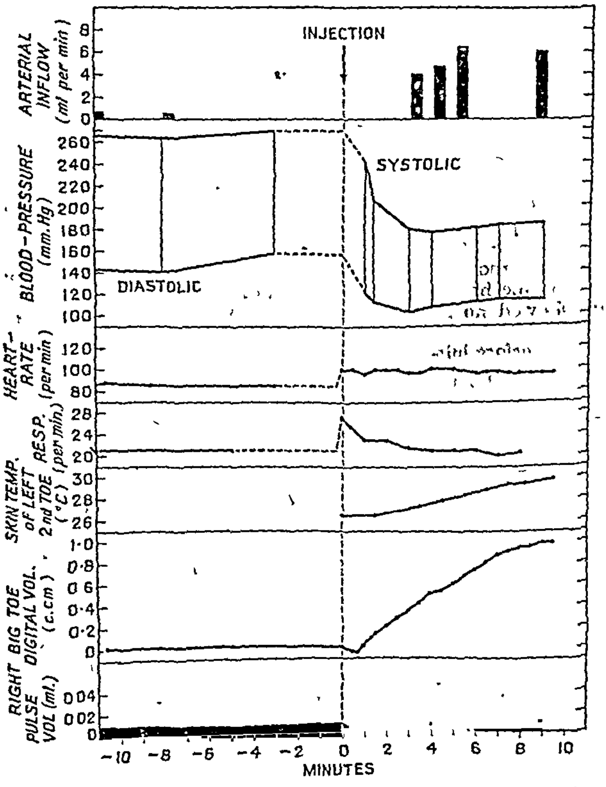

Fig. 4—The effect of an intravenous injection of 50 mg. of pentamethonium iodide in a woman, aged 47, with hypertension. The fall in blood-pressure coincides with well-marked peripheral vasodilatation.

In normal people the peripheral vasodilatation accompanied by little change in blood-pressure. patients with hypertension the vasodilatation coi with a fall in blood-pressure. Adrenaline counter this hypotensive action, and its effect on the peri circulation was investigated in a normal person the influence of pentamethonium iodide. Though a minimal intravenous dose of adrenaline was giv caused a definite rise in blood-pressure and a vasoconstriction. In this respect pentamethonium does not prevent the peripheral action of adrenaline

The effect of pentamethonium iodide has also studied in the sympathectomised limb. The occurrence some vasodilatation, when intrinsic vascular tone been regained, was unexpected, and the possibility some direct action on the peripheral vessels has been excluded.

The dose of pentamethonium iodide required to a all vasoconstrictor impulses has not yet been determ and we are now investigating the constancy and of its vasodilator action in peripheral vascular disease

SUMMARY

The peripheral vasodilatation produced by pe methonium iodide has been studied with the optical di plethysmograph.

In normal people vasodilatation begins within minute of injection and persists for at least an hour.

The value of pentamethonium iodide in the investi tion and treatment of peripheral vascular disease is being studied.

The pentamethonium iodide used in this investigation kindly supplied by the Wellcome Foundation. Our th are due to Mr. V. K. Asta, medical artist at Univer College Hospital medical school, for assistance in preparation of the charts.

NCE OF STAPH. AUREUS IN THE TERIOR NARES OF HEALTHY CHILDREN

A. C. Cunliffe
M.A., M.D. Camb.

IN BACTERIOLOGY, UNIVERSITY OF LONDON, AT
LEGE HOSPITAL MEDICAL SCHOOL; BACTERIOLOGIST,
KING'S COLLEGE HOSPITAL

T some knowledge of the incidence of a c micro-organism in the healthy body it is o assess the significance of the organism when diseased tissues, and to estimate accurately ces and importance of self-infection and ction.

long been recognised that *Staph. aureus* may be the nose and on the skin of healthy people; al. (1944), reviewing the published reports, timates of the nasal carrier-rate of *Staph. aureus* from 22 to 45%. These variations are no doubt ly to different sampling techniques and partly nces in the populations sampled. It is interesting that, whereas Miles et al. found a carrier-rate % among patients swabbed on admission to , they observed a significantly higher rate of among patients sampled during their stay in and 64% among the nurses.

nation about the incidence of *Staph. aureus* in es of children is relatively scanty, but both (1937) and McFarlan (1938) agree in finding ntly higher rates among children than among in hospital—i.e., 58·4% in children as against in adults and 57·5% as against 41·9% respec- Dr. A. M. Thomas and I (unpublished work, y Miles 1941) found that the nares of about f healthy infants born in hospital are infected *taph. aureus* within the first two weeks of life.

present survey of the incidence of *Staph. aureus* nares of healthy children was undertaken to find r there is a gradual fall in the carrier-rate with ing age. as suggested by the above results. n recorded a higher incidence (60·5%) between es of 13 and 19 than in either adults or younger n, but found no change between the ages of 12 years, though he states that there was "a sharp variation around the mean of 58·4%"; per, however, does not contain the figures upon he based this observation.

MATERIAL AND METHODS

population studied consisted of four groups of n.

up 1 comprised 156 children aged from 2 weeks years, whose noses were sampled within a few of their admission to hospital. This sample was cted but for the fact that children with signs or oms of infection of the upper respiratory tract excluded. It included 71 patients with congenital nities of the lip and palate, since no significant nces in nasal carriage were found between them ormal children.

up 2 comprised the entire population of a small ntial school of 40 children aged 3–15 years.

Group 3 was composed of 138 children, aged from 2 weeks to 5 years, attending an infant-welfare clinic; several of these children were swabbed on many occasions, but for the purposes of this survey the result of only the first swab has been included, though this was not always taken at the first attendance at the clinic.

Group 4 consisted of 112 babies aged from less than 1 hour to 2 weeks, from whom 255 swabs were taken in the maternity unit of a general hospital, where in the past several small outbreaks of impetigo neonatorum had taken place; there was no major outbreak during the four months (January–April) in which the survey was conducted, though occasional "sticky eyes" and three mild cases of impetigo were noted during this time.

Technique of Sampling.—The nose was sampled by passing a swab moistened with peptone water or nutrient broth through both nostrils; the skin by rubbing a moistened swab over a circular area, 2·5 cm. in diameter, on the back of the right wrist. The swabs were inoculated on to one half of a 5% horse blood-agar plate within $^{1}/_{2}$–2 hours of sampling. Plates were examined after incubation overnight at 37°C; all staphylococci were tested for coagulase activity by the slide technique (Cadness-Graves et al. 1943), and those negative by this test were tested in 10% plasma broth. All coagulase-positive strains were classed as *Staph. aureus* irrespective of their pigment formation or hæmolytic activity. Though the findings of Schwabacher et al. (1945) suggest that there may be a somewhat closer correlation between virulence and production of α lysin, it is certain that, by using the coagulase test only, most if not all of the potentially pathogenic staphylococci will have been recognised, because coagulase-negative strains do not produce α lysin (Schwabacher et al. 1945).

RESULTS

Carrier-rates in the First 14 Days of Life

The carrier-rates for the first 14 days of life were computed from data gathered in the maternity unit of a single hospital and can in no way be considered to represent a random sample of the infant population as a whole. Conditions in such units are very different from those of home nursing in that there is a greater risk of cross-infection.

The unit was housed in a block apart from the main hospital and contained a main 8-bedded ward of about 24,000 c.ft. capacity, one 2-bedded ward, and two single rooms; the infants were bathed in a common nursery. At the beginning of the survey swabs were taken daily or at two-day intervals; but, when it became evident that 90–100% of the children were already infected by the end of the first week, and since in no instance was a negative swab obtained in the second week once *Staph. aureus* was established, the routine was modified, and swabbing was mainly confined to the first few days of life to ascertain how quickly the nose was colonised with *Staph. aureus*. No accurate estimates of the daily carrier-rates can therefore be given after the fourth day. There was, however, a progressive increase from 8·6% on the first day to about 100% at the end of the first week, over 50% of noses being colonised by the third day (table I). These figures

TABLE I—NASAL CARRIAGE OF *Staph. aureus* IN THE FIRST MONTHS OF LIFE

—	Days of age					Months of age			
	0–	1–	2–	3–4	7–14	$^{1}/_{2}$–	1–	2–	4–6
children sampled ..	35	50	47	38	28	12	22	34	21
nd percentage (± standard error) carrying *Staph.* rus	3 8·6% ± 4·7	11 22% ± 5·9	26 55% ± 7·3	29 76% ± 6·9	27 96% ± 3·6	11 91% ± 8·1	13 59% ± 10·5	13 38% ± 8·3	8 38% ± 10·6

TABLE II—NASAL CARRIAGE OF *Staph. aureus* IN THE EARLY YEARS OF LIFE

—	Years of age					
	½–	2–	4–	6–	8–	10–15
No. of children tested	78	65	39	31	17	15
No. and percentage (± standard error) of carriers	18 (*23% ± 4·8*)	19 (*29% ± 5·6*)	15 (*38% ± 7·8*)	18 (*58% ± 7·8*)	*11* (*65% ± 11·6*)	9 (*60% ± 12·6*)

$\chi^2 = 24{\cdot}21$; N = 5; P = 0·001—i.e., similar differences between these groups would not be obtained by chance more than once in a thousand times.

approximate very closely to those obtained by Torrey and Reese (1945).

About 20% of the plates inoculated from swabs taken on the first day were sterile, compared with 4% and 2% on the second and third days respectively. The total growth on the first two days was invariably scanty and was composed for the most part of micrococci, non-hæmolytic streptococci, and diphtheroid bacilli, a finding in agreement with the work of Kneeland (1930) and Torrey and Reese (1945). A further interesting feature brought out by repeated swabbing was the rapid increase in the numbers of *Staph. aureus* appearing in the cultures; whereas only a few colonies of these organisms were generally isolated from the first positive swab, a profuse growth, often a pure culture, was invariably obtained within three days of this finding. Similar heavy growths were obtained from all except one of the swabs taken in the second week of life.

Carrier-rates in Infants Aged from 3 Weeks to 6 Months

Of the children examined in the first 6 months of life 95% were attending an infant-welfare centre; the remainder were patients sampled on admission to hospital. From the carrier-rates shown in the second half of table I it is clear that there was a rapid fall from 91·5% in the third and fourth weeks to 38·2% in the fourth and fifth months. It is uncertain what relation these figures bear to the general population, since 70% of the children attending the clinic were born in hospital, 35·5% at the same hospital as the infants of group I; 25% were born at home; and the remaining 5% were born in private nursing-homes. The number of home-born babies was, unfortunately, small, but the fact that one of two home-born children gave a negative swab in the first month and that all six were negative in the second month (table III) suggests that in these children the rates in the early weeks of life are lower than those of hospital children of the same age. No gross differences in carrier-rate were, however, apparent between children born in hospital and at home in the age-groups 3–6 months and 7–12 months.

TABLE III—COMPARISON BETWEEN NASAL CARRIER-RATES OF CHILDREN BORN IN HOSPITAL AND AT HOME

Age of child	Place of birth	
	Home	Hospital
2–4 weeks	1/2	9/10
5–8 weeks	0/6	13/16
2–8 weeks	1/8 (*12·5%*)	22/26 (*84·6%*)
3–6 months	5/10	10/23
7–12 months	2/9	2/8
3–12 months	7/19 (*36·8%*)	12/31 (*38·7%*)

Numerator = no. of children carrying *Staph. aureus*.
Denominator = total no. observed.
Percentages carrying *Staph. aureus* are in parentheses.

Carrier-rates in Children Aged from 6 Months to 1

The *Staph. aureus* carrier-rates in children a 6 months to 15 years were obtained from thr hospital admissions, an infant-welfare clin, residential school. The pooled carrier-rates groups (table II) show a gradual rise from children aged from 6 months to 2 years to children aged 9 and 10 years. Though the in each age-group in the three populations small for comparison between groups, it is signif the same rising trend was found in each popul

RELATION BETWEEN NASAL CARRIAGE OF AND INFANT

To determine whether the maternal carriage of *aureus* influenced the rate at which infants infected with this organism, swabs were tak the nose and wrist of 64 mothers within hours of admission to hospital, usually on the d delivery; 37 (58%) of the mothers were nasal and 8 (13%) were skin carriers of *Staph. aureus*

Table IV sets out the carrier-rates of infants days in relation to the carrier state of the Though for each day the carrier-rate was higher in the children of nasal carriers, the χ^2 test that these differences could readily have occ chance; and, whereas it is possible that, if larger were sampled, colonisation with *Staph. aureus* shown to be more rapid in the children of ca may be inferred with certainty that in this

TABLE IV—RELATION BETWEEN MATERNAL CARRI AND DAILY CARRIER-RATE OF INFANTS

Age of child (days)	Maternal nasal carriage			
	Positive children		Negative children	
	No.	% carrying *Staph. aureus*	No.	% carrying *Staph. aureus*
0– ..	12	*25·0*	8	Nil
1– ..	22	*22·7*	17	*17·6*
2– ..	26	*57·6*	12	*50·0*
3–4 ..	18	*88·3*	11	*72·7*

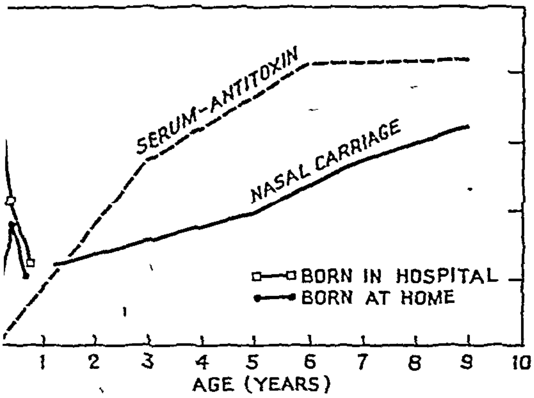
For whole group, $\chi^2 = 2{\cdot}0047$; N = 3; P = 0·6—i.e., d as great as these might be obtained by chance in three c samples of similar size.

factors were of greater importance in the col of infants' noses than was maternal infection.

This conclusion is strengthened by data o from an outbreak of neonatal impetigo in the sa twelve months later. Staphylococci of the same type (47B) were isolated from both the nose and of all six affected infants and from the noses of of six healthy children. Less than half the yielded positive nasal swabs; these strains were typed, but the odds would be very great again chance occurrence of staphylococci of the same type in the noses of more than one of these (Williams 1946). Most of the infants, therefore, have been infected from other sources. It is notew that type 47B was recovered from the wrists of four one of whom subsequently developed a whitlow which staphylococci of the same type were seven of ten nurses were nasal carriers of *Staph.* but from none of them were type 47B staphy isolated. The original source of the outbreak undiscovered; it is, however, highly probable th hands of nurses provided a ready vehicle for the of the infection.

DISCUSSION

The data presented here cannot be consider necessarily characteristic of a random sample o



ion of staphylococcal antitoxin levels in serum (Bryce and 1932) with nasal carrier-rates: interrupted line, percentage containing 40 or more arbitrary units of staphylococcal α in per ml.; continuous line, nasal carrier-rate of children.

opulation. The carrier-rates for the first two of life were estimated only for infants born in le hospital. However, conditions in this unit ot materially different from those found in most ity units, and there is considerable evidence to that similar high rates of nasal carriage obtain t hospitals. Thus, in unpublished investigations d rates over 80% in two other institutions, a f affairs similar to that observed in the New York al by Torrey and Reese (1945), and that observed unit investigated by Duncan and Walker (1942), *Staph. aureus* was found in the throats of 95% dren within 8 days of birth. Other investigations ernity units have largely been carried out during, r, outbreaks of staphylococcal infections; McFarlan reported a carrier-rate of 80% among 41 babies, whom had "pemphigus," and Dr. E. J. Stokes nal communication) found rates of 80–100% in ndon and numerous Hertfordshire maternity units. evidence from a small number of babies swabbed first and second months suggests that the nares t colonised with *Staph. aureus* with the same speed gularity in infants born at home as in those born spital. This might be expected on the grounds esser opportunity for infection; for, whereas the oir of *Staph. aureus* in the home is probably largely d to the nasopharynx and skin of the mother and in hospitals there is a vast pool of potential ion in the noses and on the skin of infected infants, ir fomites, and in the dust (Hobbs 1944, Knott laikley 1944). The evidence presented here indithat infants in hospital are not usually infected eir mothers but more commonly indirectly from babies, with the hands or clothing of attendants he air as probable vehicles of infection. A similar retation might be made of Duncan and Walker's) findings that staphylococci were usually found e throat of the infant earlier than in the breast-milk e mother. Further, by the serological and phage g of *Staph. aureus* Elliott et al. (1941) and Hobbs) have produced strong circumstantial evidence nurses who are persistent and profuse carriers may rise to outbreaks of neonatal staphylococcal infec-

It seems therefore highly probable that carriersimilar to those in table I are usual in hospital nts, and it is certain that infants are more often ted from the hospital environment than from their ers.

view of the work of Hallman (1937) the finding in this ey, clearly illustrated by the accompanying figure, gradual rise in the nasal carrier-rate for children aged 2 to 10 years was unexpected, as was the very low ence in those aged from 6 months to 2 years. This is of greater interest in the light of Dr. R. E. O. William's finding (personal communication 1947) of a gradual fall with age in the incidence of *Staph. aureus* in the noses of adults. Swabbing hospital outpatients on their first attendance he obtained nasal carrier-rates of 53%, 52%, 43%, and 38% in the second, third, fourth, and fifth decades respectively, and 45% for ages over 50 years.

It is tempting to speculate on these variations in the nasal flora. The initial high incidence in the first weeks of life, which is perhaps true only of children born in hospital, probably results from the entry of highly susceptible individuals into a heavily infected environment. That newborn infants are highly susceptible to *Staph. aureus* is borne out by the difference between adult and neonatal lesions and by the lack of localisation which characterises the severer types of staphylococcal infection in children. The low incidence of clinical staphylococcal infections among the mothers of infants with septic staphylococcal lesions is a striking feature of most outbreaks of severe impetigo neonatorum and suggests that this high susceptibility of infants is due mainly to a lack of cellular immunity, since at birth children are endowed with circulating staphylococcal antitoxin acquired passively from their mothers (Bryce and Burnet 1932, Murray 1935).

The fall in the nasal carrier-rate in the first two years may bear some relation to the fact that most young children live in a small closed community; immunity is perhaps acquired against the strains present in these surroundings, the subsequent rise in incidence being possibly the result of the child's gradually increasing contact with fresh strains of *Staph. aureus* in the outside world, particularly in a school community. The gradual fall with age of the incidence of *Staph. aureus* in the nares of the adult population, as noted by Williams, may be a reflection of an increasing immunity, but may, on the other hand, result from a less intimate contact with the community than occurs during school years.

It is interesting to compare the staphylococcal antitoxin levels found by Bryce and Burnet (1932) in human sera with the nasal carrier-rates for the same ages. The interrupted line in the figure summarises their findings; the rapid fall in antitoxin level in the first few months of life is, no doubt, due to a loss of congenital passive immunity (cf., diphtheria and scarlatinal antitoxin); the gradual rise in the age-group 2–10 years, however, bears a well-marked resemblance to that obtained by plotting the percentage incidence of *Staph. aureus* in the nose against age, but it is a matter for conjecture whether it is in any way related to the factors causing the rise in nasal carrier-rate in this age-group. Bryce and Burnet (1932) isolated white staphylococci of low toxicity from the skin of healthy people and suggested that such strains might play a part in bringing about this immunity; *Staph. aureus* of apparently normal toxicity, as judged by the coagulase test, will presumably have the same effect when carried in the nose. However, though it is possible that the nasal carriage of these organisms may be beneficial in stimulating defence mechanisms, it must be remembered that, as phage typing has shown, many wounds become infected with staphylococci previously carried in the person's own nose (Williams and Miles 1949); thus, if the staphylococcal α antitoxin is a response to the stimulus of the person's own nasal staphylococci, it does not appear to confer a very marked immunity to wound infection.

SUMMARY

The incidence of *Staph. aureus* in the anterior nares of 446 children aged from 1 day to 15 years has been surveyed.

In children born in hospital the nose was colonised with *Staph. aureus* very rapidly, the incidence increasing progressively from 8·6% on the first day to about 100% at the end of the first week.

After the age of a month there was a steep fall in the carrier-rate to 23·1% between the ages of 6 months and 2 years; thereafter there was a progressive rise to 64·7% at 10 years.

Evidence collected from a small number of children born at home suggested that in the early weeks of life the incidence of *Staph. aureus* in these children may be lower than that found in hospital children of the same age.

The sources and channels of infection are commented on and the relation of the staphylococcal carrier-rate to antitoxic and antibacterial immunity is discussed.

I wish to thank Dr. V. D. Allison for typing many strains of staphylococci and Dr. A. A. Miles for his continued interest and advice.

SERUM-ENZYME CHANGES IN PERFORATED PEPTIC ULCER

HENRY WAPSHAW
M.D. Glasg., F.R.F.P.S., F.R.C.S.E.
ASSISTANT SURGEON, WESTERN INFIRMARY, GLASGOW

THE differential diagnosis between perforated peptic ulcer and acute pancreatitis is sometimes difficult. In previous times, the need for early operative treatment was considered equally clamant in both conditions, so it made little odds if the one was mistaken for the other before operation. Now that acute pancreatitis has come to be regarded as a self-limiting disease, this problem has assumed a different complexion. It is true that ordinarily a perforated ulcer can be confidently diagnosed at the bedside, but in the few atypical cases where doubt arises the surest way of deciding the issue short of laparotomy is to carry out one of the tests of pancreatic function. This investigation was prompted by the discovery of a case of perforation in which the serum diastase and lipase readings were so high and the symptoms and signs so obscure that an erroneous diagnosis of acute pancreatitis was made. The following are the salient features.

A middle-aged man, who had suffered from indigestion for many years, was seized with severe upper abdominal pain for 46 hours before his admission to the Glasgow Western Infirmary. When first seen there, his general condition was poor and his skin had a cyanotic tinge. The abdominal signs were those of a generalised peritonitis. The value for diastase was 740 Somogyi units per ml. of serum and for lipase 4·1 ml. of $N/20$ NaOH.

The patient was given morphine and intravenous glucose-saline, but he died two hours later.

At autopsy, an anterior perforation of the first part of the duodenum was found. There was widespread peritonitis. The peritoneal covering of the pancreas was congested and overlaid with patches of fibrin but the gland itself was healthy.

TABLE I—ENZYME READINGS IN 30 CASES OF PEPTIC ULCER IN ORDER OF DURATION OF

Case no.	Site of perforation	Duration of illness before study (hr.)	Serum-diastase (Somogyi units) (normal 70–200)
12	Stomach	2½	160
5	Duodenum	2½	46
2	Duodenum	3	177
26	Pylorus	3	145
28	Duodenum	4	..
9	Duodenum	4	145
29	Pylorus	4	..
15	Duodenum	4	53
7	Duodenum	4½	184
16	Stomach	5	133
21	Duodenum	5	76
4	Duodenum	6	65
10	Duodenum	6	84
18	Duodenum	7	88
17	Duodenum	7	66
14	Duodenum	7	355
30	Duodenum	7	..
25	Duodenum	7	168
23	Duodenum	7	106
22	Duodenum	8	106
20	Anastomotic ulcer	9	106
11	Duodenum	9	266
8	Duodenum	10½	248
6	Duodenum	11	66
13	Duodenum	11	266
19	Duodenum	12	88
24	Pylorus	12½	88
3	Duodenum	15 (died)	640
27	Duodenum	24 (died)	177
1	Duodenum	48 (died)	720

The patients were all male.

So far as can be ascertained, raised serum-lipase have not been previously recorded in this condition, there are two references to aberrations in the serum-di level. In a mixed series of 17 cases of perforated ulcer, Probstein and others (1939) noted a well-increase in the serum-amylase level in 4 patients these 4, 3 were treated surgically and no lesion from the perforation was found. A presumptive of acute pancreatitis was made in the fourth case and operation was therefore done. The patient died autopsy revealed a perforated gastric ulcer attached but not penetrating, the surface of the pancreas. ulcers in the other 3 patients with raised readings lay close to the pancreas, whereas all the other ca anterior perforation gave normal readings. On basis Probstein and his colleagues concluded that ro diastase estimations might not only aid in the recogn of cases of acute pancreatitis but would also help locate a perforated ulcer, if there was one. H (1942), on the other hand, has produced evidence disordered pancreatic function in cases of ant perforation. His studies were confined to the diastatic index. Out of 40 cases, he found 4 with siderably raised values. Each of these 4 patients operated on, with one death, and in none was there demonstrable signs of pancreatic disease.

Since it seems likely that the enzyme aberra described above might weigh against operation, ticularly if the clinical findings presented at features, it was decided to study the problem in m detail.

MATERIAL AND METHODS OF STUDY

The series comprised 30 cases of perforated pe ulcer. In each one the ulcer was situated anteriorly unrelated to the pancreas. The distribution of the les according to site was: duodenal 24, pyloric 3, gastric and anastomotic 1. All, except the one already refe to, were operated on and their perforations closed.

The *diastatic activity* of the blood was estimated by iodometric technique, described by Somogyi in 1938.

normal indices is 70–200 arbitrary units of diastase f serum. The range is wide, but the values for any son remain constant under physiological conditions. gly, the method is suitable for the detection of small s from the normal.

rum lipolytic activity was estimated by the Loewen- ethod as modified by Cherry and Crandall (1932). es are expressed in terms of the amount of alkali to neutralise any fatty acid resulting from the action rum lipase on an olive-oil emulsion. The range of was taken to be 0–1·5 ml. N/20 NaOH per ml. of which agrees with that accepted by Comfort and (1940).

COMMENT ON RESULTS

nzyme readings are given in table I. The cases to fall naturally into three groups: (1) the 13 during the first six hours, (2) the 15 studied the seventh and twelfth hours, and (3) the 3 r. In each of the first group, the chemical findings in the normal limits for both tests. Among those ne under observation during what may be called ical phase of their illness there were 4 with raised readings (cases 8, 11, 13, and 14). The tres were also raised in cases 13 and 14 but in the others. Of the 3 cases in the third group, gave normal enzyme readings, whereas the n the remaining 2—case 3 of fifteen hours' and two days' standing—were substantially elevated. ignificance of these results can only be appreciated paring them with those of cases of acute pancrea- recently published work in which the same tests nployed (Wapshaw 1948) the increase in the e activity of the blood in acute pancreatitis was o be greatest during the first few hours, the thereafter showing a steady decline. The return al levels occurred between the third and seventh he findings in two representative cases are given II.

I—ENZYME FINDINGS IN 2 PATIENTS WITH ACUTE PANCREATITIS

nosis	Time of observation	Serum-diastase (Somogyi units)	Serum-lipase (ml. N/20 NaOH)
subacute eatitis	6th hr.	5000	9·8
	3rd day	460	5·8
	6th day	220	3·0
acute rrhage reatic rosis	14th hr.	4000	5·0
	2nd day	2100	
	3rd day	475	0·5
	7th day	320	0·5

e who have carried out serial observations on cases is "colourless jaundice," as Garrod (1920) was say, have with few exceptions reported similar . Taking these figures as a measure of the n that may be expected in acute pancreatitis, it seen that there are only 2 perforation cases out 30 studied—cases 1 and 3—with findings that cause real difficulty in diagnosis.

t significance can be attached to the positive ? Do they really denote pancreatic dysfunction ? ns reasonable to infer from the analysis that itis, which usually sets in about the seventh hour leed caused death in the 3 late cases, may have he damaging factor. But further study of this ect of perforated peptic ulcer is needed before conclusions can be drawn as to its causation and cy.

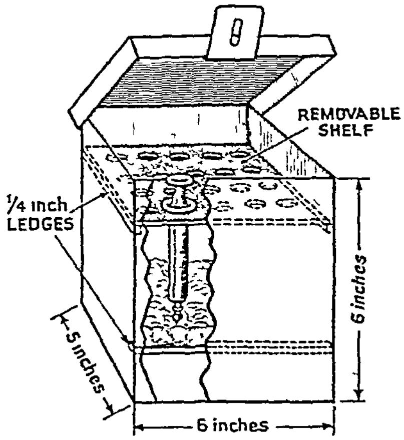
A METHOD OF CENTRAL STERILISATION OF SYRINGES IN HOSPITAL

JOHN MURRAY
M.D. Camb.
DIRECTOR OF PATHOLOGY, QUEEN CHARLOTTE'S MATERNITY HOSPITAL, LONDON

It is generally accepted that the usual methods of sterilising and storing syringes in hospitals are far from satisfactory, and the staffs of many hospitals are trying to organise a syringe service, if not a complete central sterilisation unit.

To prepare all-glass syringes by the method recommended by the Medical Research Council[1] means putting up each syringe separately in a glass test-tube. This method, though satisfactory in the laboratory and perhaps, with care, in small units, is cumbersome, time-consuming, and expensive for large hospitals. The greatest disadvantage of the test-tube method lies in the large number of 1 ml. syringes used. In some big hospitals it has proved impossible to provide individual packaging of the small syringes and needles in this way.



To overcome these difficulties, a simple method has been devised for sterilising many syringes together in a box. These boxes can be easily and cheaply made of copper, plated if necessary, with a hinged lid and hasp. Inside are two pairs of ¼ inch ledges, an upper pair running from front to back, and a lower pair running from side to side. All-glass syringes are hung through holes in a removable metal shelf resting on the upper ledges, with their needles mounted and plunged through a thick pad of gamgee tissue supported at the level of the bevels of the needles by the lower ledges, as shown in the accompanying diagram. This pad is made from a piece of gamgee tissue sewn over a rectangular wire frame and fits snugly all round to the sides of the box. For use, the cleaned syringes are dropped through the holes in the shelf, so that their needles penetrate the cotton-wool pad, and the box is sterilised in the hot-air oven for an hour at 160°C. The needs of each ward must be investigated, and boxes of an appropriate size to carry the requisite number of syringes to cover the average day's work can be made.

The needles are protected mechanically and bacteriologically by the pad of gamgee tissue, and the complete outfit will remain sterile for at least a day, even though the lid is often opened. In practice, it seems necessary for the set to be resterilised at the end of each day, and for each ward to have two boxes, one in use and one being sterilised. The ward personnel would then only need to rinse out a syringe after use and place it in a separate receptacle.

Hypodermic syringes (1 and 2 ml.) are conveniently sterilised in sets of twenty, in boxes measuring 6 × 5 × 6 inches, and twelve 5 and 10 ml. syringes can be accommodated in similar boxes if the depth is increased to 8 inches. It is unsatisfactory to sterilise large and small syringes in the same box.

---

[1] Medical Research Council War Memo no. 15, 1945.

It may be thought, with reason, that the initial expense is against the introduction of such equipment; but, since most authorities agree that a centralised syringe service is ideal, the method here suggested involves no more expense than does the preparation of syringes in separate containers. On the other hand, adoption of the system should result in a great saving of labour and a reduction in breakages of syringes.

OVARIAN PREGNANCY

A. H. BARBER
M.A. Oxfd, M.B. Birm., M.R.C.P., F.R.C.S.
GYNÆCOLOGICAL SURGEON, BOUNDARY PARK GENERAL HOSPITAL, OLDHAM

THOUGH tubal pregnancies are common, pregnancies in the abdominal cavity occur much less often. There can be no doubt that many abdominal pregnancies start in the tube, and the fertilised ovum, instead of being conducted down to the uterus, is expelled in the reverse direction through the abdominal ostium as a tubal abortion. The ovum then falls through gravity into the pouch of Douglas, and this is what seems to have happened in the case recorded by Nicolson.[1] More recently Billington and Goodchild[2] have reported the remarkable case of a young native woman in Uganda who appears to have had a primary pregnancy in the left ovary and was delivered of a living child. Laparotomy was apparently performed at the request of the patient, and what proved to be the uterus had not unnaturally been hitherto regarded as a fibroid.

Though an attempt has been made to determine the incidence of implantation of fertilised ova in the peritoneal cavity, records of operations are insufficiently detailed to allow of division of these cases into those which are primary and those which are secondary to tubal abortions. Quilliam[3] states that about 11 reports of abdominal pregnancy have been published annually in the past thirty years, and he estimates that about 1 abdominal pregnancy occurs in every 12,500 pregnancies of all types seen in hospital practice.

True primary abdominal pregnancy must, however, be much more rare; and since the possibility of the implantation of a fertilised ovum on the peritoneum has not yet been satisfactorily demonstrated, it seems that all true primary abdominal pregnancies must be situated in the ovary. In the following case the pregnancy was in the left ovary.

CASE-RECORD

A primigravida, aged 33, was first seen at Boundary Park General Hospital, Oldham, on Nov. 18, 1947. She was then about 4½ months pregnant, the date of her last menstrual period being given as June 20, 1947. Six years previously she had been treated elsewhere for sterility. She was sent up to hospital because she was having a very slight daily loss of blood per vaginam, and her doctor had felt a mass in the right iliac fossa.

On examination she appeared to have a normal pregnancy, its size corresponding to the period of gestation. Nothing abnormal was noted except a smooth rounded mass about the size of a small orange in the right iliac fossa. This was considered to be a fibroid attached to the right side of the uterus and projecting into the broad ligament.

The patient felt perfectly well and had no suggestion of pain or discomfort. She did not intend to come into hospital for delivery but had placed herself under the care of a midwife who was her cousin. This relationship made the midwife particularly careful, and she therefore arranged for radiography to be done.

Radiography.—The patient was radiographed at Ashton-under-Lyne Infirmary on Feb. 23, 1948, and Dr. Blair Hartley reported as follows: "There is a single fœtus of some 30–32 weeks' development. It is attempting to present as an but the head lies well back and slightly over to the suggestion is therefore that there is some soft-tissue in the right anterior quadrant of the pelvic inlet. P prævia is therefore a possibility if not a probability."

Because of this report the patient was again sent to on March 5. The fibroid could still be felt on the but the head was entering the pelvis, and there reason to anticipate any trouble. More to allay appre than for any other reason it was suggested that the should come into hospital for delivery, and it was that she should attend the antenatal clinic.

On March 15, however, she was admitted to hospita emergency. She had been ill for about a week with and on admission had a temperature of 104°F. considerable respiratory distress, and tubular was heard at both bases. The patient looked toxic, albumin in the urine, and her blood-urea was 54 100 ml. She was doubtful about recent fœtal move the fœtal heart was queried. Penicillin was given and her temperature came down, her general condition improve. There seemed now no doubt that the fœtus dead, and a bougie induction was unsuccessfully by a resident obstetric officer. Previously, rectal ex by the midwife had shown that the head was well the pelvis, and no obstetrical difficulty was anticipated the patient did not go into labour, a further e was performed, and it was quite clear that the head the pouch of Douglas, and that the "fibroid" was in body of the uterus. The patient, however, was far too laparotomy to be considered, presenting a picture of toxæmia, which was attributable to protein absorption the dead fœtus. She died on March 29, two days expected date of delivery.

Necropsy (Dr. C. H. Adderley).—Though abdominal nancy had been diagnosed, when the abdomen was some of the onlookers thought there was a uterine p so closely did the mass simulate a normal uterus. The p situated on the back of the left broad ligament and on the left ovary, presented anteriorly, and where grew above the level of the broad ligament it was po reinforced by omentum. Running obliquely across the were the left tube and round ligament, and there adhesions to other abdominal structures. A well-de full-term male fœtus weighing 6 lb. was removed.

DISCUSSION

This case presents several features of unusual in There seems no reason to doubt that the p occurred in the left ovary, though unfortunat section of the sac was taken to prove the pres ovarian tissue. It seems certain too that a f living child could have been delivered had n mother developed influenza, the toxæmia from appeared to be responsible for the death of the Thereafter the patient developed signs of severe to apparently due to protein absorption from the fœtus lying in the peritoneal cavity. Billington Goodchild[2] obtained a living child in similar stances, and both in their case and in this one the was regarded as a fibroid.

Though such cases are extremely rare, it seems able, whenever an apparent fibroid is felt in pregn particularly in either iliac fossa, to entertain the bility of the pregnancy being ovarian; slight bl at intervals throughout the pregnancy gives addi support to the diagnosis. It is just possible that v examination early in pregnancy would have revealed abnormality; there is no doubt that late in pre the condition is most difficult to diagnose, es since the placenta is anterior and produces a la tissue at least equal in thickness to that of a n uterus. And this case proves conclusively that graphy does not help. There must be few films of full-term extra-uterine pregnancies in existence, and one was taken almost by accident. It is true that Dr. Hartley detected some odd condition and noted "s tissue structure in the right anterior quadrant of pelvic wall." The possibility of extra-uterine gest

occur to the radiologist, and Dr. Hartley has me that, had the suggestion been made to him cian, he does not think he would have accepted as a very extreme possibility.

SIMPLE ŒSOPHAGEAL CAST

J. M. WILLCOX
M.C., M.B. Camb.
Department of Medicine, Postgraduate Medical School of London

AGEAL casts are exceedingly rare. Patterson ported a case and found records of 17 others, ck to 1877. No further examples have been since 1935.

son thought the most likely mechanism was a œsophagitis, followed by excessive epithelial ion, sporadic separation of the mucosa, ulcera- he cardiac end, and eventual invagination and of the cast. In the present case neither the or barium swallow suggests achalasia, but the trongly supports the idea that separation and begin at the cardiac end of the œsophagus. g to Beattie and Dickson (1943), mucosal d even casts are a well-recognised sequel to the g of corrosives, and some of the cases collected rson probably had similar causes—e.g., swallow- hloral, chloroform, very hot fluids, or neat l spirit (one case each). Sometimes it is doubt- was cause and which effect—e.g., the sticking s of bread or meat. In one case there was an e tendency. Usually there is no adequate ion. In 3 cases there was recurrence; two 1 case, and three casts in 2 cases. Casts have own to follow diphtheritic œsophagitis (Raw nd membranous œsophagitis may develop in acute and chronic conditions (Adami and 1910).

CASE-RECORD

nglish housewife of Huguenot descent, aged 40, ught up an œsophageal cast in 1933. During the years she expelled two more casts, and in 1948 cast. In the intervening ten years she twice had thought were premonitory symptoms, consisting of a, but casts were not shed.

h occasion there has been the same train of events. tely after her tea she develops a burning sensation he xiphoid process. This burning rises to the upper the sternum. Excessive saliva then begins to flow, e tries to swallow, but it is painful to do so, and the ems to stick half-way down. This stage lasts about hour. It is followed by a peculiar "turning over" in the abdomen; she is unable to swallow the y more, and she vomits up a "tube," which hangs r mouth but remains attached to the back of her On the first occasion she tried to swallow the tube could not do so; so she bit it through and swallowed that was left. On the second and third occasions the tube through with scissors. On the last occasion ulled the whole tube away.

ch time she has brought up a little blood with the tube rom half to one hour later has vomited about half a pint oodstained fluid. There has been no further vomiting ot on the last occasion, when she continued to vomit for a fortnight but brought up no blood; lying on her ide aggravated this vomiting.

ter bringing up the tube salivation continues. She to swallow the saliva but finds it causes so much retro- al pain that she gets rid of it into a towel or basin. Pain salivation becomes less after a fortnight, and after about weeks she feels normal.

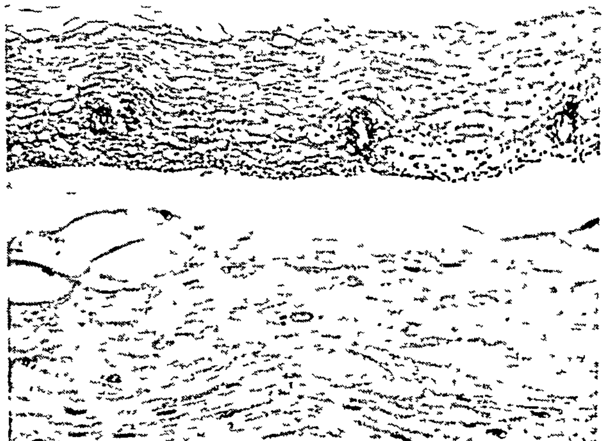
uring the first few days she takes only a little soda- r and milk. She then graduates through semi solids normal diet. The semi-solids—e.g., 'Farex,' 'Brand's nce'—at first seem to stick at about the level of the nd costal cartilage, causing pain just to the right of the num. Stretching the arms above the head and leaning backwards seems to help the food go down. In the early stages fluids are more painful to swallow than semi-solids.

The patient's general health is good. Between the episodes she has no dysphagia or dyspepsia. She has noted for three or four weeks before each episode a general swelling of the abdomen, the effect of which is that her clothes are tighter than usual round the waist. This swelling subsides when the cast is brought up. There is no associated pain or difficulty with swallowing. For about eighteen months in 1945–46 the patient had intermittent discomfort in the right hypochondrium, diagnosed as cholecystitis. It cleared spontaneously and radiography did not reveal gall-stones. She has never had any skin trouble or abnormality of the nails. She has not passed casts of the respiratory tract, bowel, or uterus. She is rather liable to sore throats, and has three or four attacks a year, but they are never severe. She has not had laryngitis. She eats a normal mixed diet and is fond of hot tea and coffee, but she does not take them unduly hot, she thinks. She also likes moderately hot pickles, which she eats only occasionally. She takes no alcohol and is a non-smoker.

Previous History.—She has had no serious illnesses. There have been two pregnancies: one in 1932 ended in miscarriage; one in 1943 was normal. Since then the patient has steadily put on weight. There is no family history of the passage of casts. Her mother had dyspepsia; her father and brother are well; a sister died of appendicitis at the age of 8 years; a half-sister is well.

On Examination.—An intelligent woman of obsessional type. Weight 11 st. 9 lb., height 5 ft. 1 ½ in. General appearance healthy. Skin, nails, and hair normal. No dryness or scaling of the skin. Oral mucosa, tongue, and teeth normal. Pharynx (four weeks after the last episode) a little injected. Tonsils small and pitted. No abnormal lymph-glands. Respiratory and cardiovascular systems normal. Blood-pressure 130/95 mm. Hg. Abdomen fat, with mild epigastric tenderness. No masses felt. No distension. Central nervous system normal.

Investigation.—Barium swallow normal in upright and semi-prone positions. No constriction or ulceration of œsophagus. With barium meal in the stomach there was no regurgitation into the œsophagus. Outline of the stomach showed a well-marked rugal pattern. Emptying normal and duodenum



Low power

High power

Section of œsophageal cast, lumen uppermost, showing tips of papillæ.

normal; some coarseness of jejunal valvulæ conniventes. Blood Wassermann and Kahn reactions negative. The patient was not willing to undergo œsophagoscopy. The temperature at which she drank a hot beverage five months after bringing up the last cast was 59·5°C; this is almost exactly the mean found in an investigation of 236 medical students, where two-thirds of the observations fell between 54° and 66°C (Hunt 1947).

The most recent cast was not examined because it had disintegrated by the time the patient came to hospital. The cast brought up in 1934 was examined at the West London Hospital and is a thin-walled tube about 8 in. long and ½ in. in diameter. Microscopically the wall is composed of layers of squamous epithelium only. Some of the cells are œdematous. Photographs of the section are reproduced (see figure). They show the typical appearance of œsophageal lining. There are no signs of inflammation.

ÆTIOLOGY

There are no obvious causal or precipitating factors in the present case. Three of the episodes occurred in September, and one in June. It is difficult to see any significance in this or in the fact that each episode has occurred after tea. The patient can offer no satisfactory explanation. Three episodes have been preceded by some mental strain: change to a responsible job; Munich crisis, and the loss of a favourite dog; and husband ill with a series of carbuncles. She has had other and more severe strains with no ill effects.

I wish to thank Dr. J. C. S. Paterson for permission to publish the case; Dr. F. Avery Jones for helpful advice; Dr. R. G. Waller for the pathological report on the specimen; Dr. J. M. C. Corrall for the radiological report; and Dr. K. Staynes for doing the drinking test.

PERFORATED JEJUNAL DIVERTICULITIS

G. E. Moloney
M.B. N.Z., M.R.C.P., F.R.C.S.E.
ASSISTANT SURGEON

J. N. Ward-McQuaid
M.B. Lond., F.R.C.S.
SURGICAL REGISTRAR

RADCLIFFE INFIRMARY, OXFORD

Diverticulosis of the jejunum is an occasional incidental finding at laparotomy and necropsy. Since the contents of the bowel at this level are fluid, and the mouths of these diverticula are usually wide, inflammation in them is rare. In 1945 Walker reviewed 19 reported cases of jejunal diverticulitis and added 3 more of his own; additional cases have been recorded by Benson et al. (1943), Rudder (1943), Shutkin (1945), Scholefield (1946), and Williams and Walker (1946). The following case is therefore the 28th reported.

An agricultural labourer, aged 57, was admitted to the Radcliffe Infirmary on June 24, 1948. Three days previously, while working in the fields, he had developed a dull ache in the centre of his abdomen. He had continued working that day and the next, in spite of the central pain persisting and becoming stabbing. On the day of admission he had eaten his normal breakfast but could not work, because the pain, which had remained central, had increased. In the past year he had lost a stone in weight. Neither the previous history nor the family history was relevant.

On examination the signs of general peritonitis were present. Tenderness was most definite in the left lower abdomen, and, a straight radiogram giving no assistance, a provisional diagnosis of perforated colon diverticulitis was made.

Operation.—Under general anæsthesia a fixed mass was felt in the left iliac fossa. The abdomen was explored through a left lower paramedian incision. General peritonitis was confirmed, and a mass consisting of a loop of hypertrophied jejunum and pelvic colon was found. Fibrinous adhesions were gently separated, and a fæculent abscess was opened.

Excised segment of upper jejunum, showing several including one gangrenous and perforated.

Multiple diverticula of the jejunum were found, two forming part of the abscess wall. One was perforated and contained a fæcolith. The of jejunum began 40 cm. from the duodeno-jejunal the intestine both above and below the affected being normal. The loop was resected, end-to-end mosis was performed, and the wound was closed drainage.

Progress.—Convalescence was uneventful, and the returned home on the twelfth postoperative day. Si later he was in good health and had gained well over in weight.

The Specimen.—The excised segment consisted of of jejunum showing nine diverticula, all on the border and all projecting from the same side mesentery. The perforated gangrenous measured 5 × 4 × 3 cm. and had a neck 1 × A fæcolith occupied the greater part of the The narrow neck was not blocked, but possibly may have been caused by a "ball-valve" action, inflammation resulting, leading to gangrene and

COMMENT

Wasting appeared to be the only common ætiological factor in 4 cases of diverticulosis Rosedale and Lawrence (1936). Our patient a stone of weight in the past year, but this restored after operation.

van Ravenswaay and Winn (1943) state that symptoms of acute jejunal diverticulitis are most found in the left upper abdomen, or sometimes para-umbilical region. In the present case sym were most marked centrally and in the left lower

The formation of a concretion in an uninflamed diverticulum is rare. Walker (1945) stated that a tion had not been found in a case of jejunal diverti nor was one reported to be present in any of the cases we traced. Walker described a concretion inflamed ileal diverticulum. The presence of a conc in the inflamed jejunal diverticulum in the present appears to be unique.

We are indebted to Dr. G. A. C. Summers for the pho

ANÆSTHETIST, ST. GEORGE'S HOSPITAL

last few years much has been written about the uses of intravenous procaine, and the subject ntly reviewed by Mushin and Rendell-Baker.[1] g has been recommended as a drip-infusion to in in the postoperative period.[2] We have had erience of this use of the drug, but we formed ression that to obtain much beneficial effect it ssary to give quantities rather too near the danger rief intravenous injections seemed to avoid this since the administrator could watch for signs ty and immediately stop the injection.

f the main factors in the ætiology of postoperative sis is believed to be the patient's inability to iolently enough to clear the bronchial tree of is. For patients with postoperative atelectasis wing technique has therefore been adopted.

on as atelectasis is diagnosed, and provided the s general condition allows it, he is placed in a in his bed to encourage drainage from the portion of lung. The procedure is explained to d it is emphasised that success depends on his to cough vigorously and so clear his chest as ely as possible. Procaine is then slowly injected nously. The injection is continued until the feels " numb " or shows any signs of stimulation ervous system, such as dizziness, pins-and-needles hands or feet, or muscular twitching. When the l effect is obtained, the patient is told to cough; same time the side of the chest is percussed y to help shift the bronchial secretions. In s who seem unable to cough strongly enough by ry effort the larynx might be stimulated.

dose and rate of injection must be judged for se by the response to the drug; 20 ml. of 0·5% e is drawn up into the syringe, and about half of usually injected over 2–3 minutes. If possible, dle is kept in the vein during the coughing and ion. More procaine can be injected a minute or if the first attempt at clearing the bronchial tree t seem to have been successful.

ave not given barbiturates or any other drugs to against toxicity, feeling that they might mask scular twitching which is a valuable indication cient dosage. It is advisable to have a rapidly barbiturate, such as thiopentone, ready for iate injection if convulsions develop. We have ad to resort to this, nor have we tested the patient and for idiosyncrasy to procaine.

ommon with other forms of treatment for atelec- e success of procaine largely depends on its being within a few hours of the condition developing. nlikely to be of any benefit when atelectasis has stablished for several days, or when pain is not portant factor in preventing effective coughing. well be used prophylactically when there is a risk of atelectasis, and we have used it in this fter upper abdominal and thoracic operations.

have tried this method in many cases during the vo years and have been gratified by the results. ve noted no untoward effects, though we have at eared, when the patient has coughed very violently, recent abdominal incision might disrupt.

Reviews of Books

Preoperative and Postoperative Care of Surgical Patients

HUGH C. ILGENFRITZ, A.B., M.D., F.A.C.S., formerly assistant professor of surgery, Louisiana State University. London: Henry Kimpton. 1948. Pp. 898. *52s. 6d.*

Care of the Surgical Patient

Including Pathologic Physiology and Principles of Diagnosis and Treatment. JACOB FINE, M.D., surgeon-in-chief, Beth Israel Hospital; professor of surgery, Harvard Medical School. Philadelphia and London: W. B. Saunders. 1949. Pp. 544. 40*s.*

THE non-operative aspect of surgical treatment is more important today than it has ever been. Research in such matters as shock, chemotherapy, burns, and thrombophlebitis—to mention but four of the subjects it touches—has widened the possibilities of treatment in the surgical wards, and added to the responsibilities of the surgeon. With further perfection of operative technique and with the greatly increased safety of anæsthesia, surgery is more adventurous than ever before, and so it is vitally important that the surgical team should know and use everything that can add to the patient's chances. There is so much that can be done to convert the poor risk into a good risk. The undergraduate must spend his clinical years learning the pathology and diagnosis of disease: the young resident is keen to acquire skill in operating; but the aim of the surgical team as a whole must be the ultimate safety of their patients. The enthusiasm of the team must, in the long run, be not for beautiful operations performed with a perfection of surgical technique, but for surgical wards filled with patients who are making smooth recoveries from major surgical procedures, and who will be discharged fit. The type of doctor who is capable of acquiring the most perfect technique may not be the same as he who can raise the therapeutic standards of his wards. Therefore it may be no bad thing that the scope of the non-operative side of surgery should be brought into the limelight by the publication of books dealing exclusively with the care of the patient outside the operating-theatre.

The two textbooks here reviewed are both by American professors of surgery, and both are written with enthusiasm. Professor Ilgenfritz, who aims at giving the physiological basis for every therapeutic measure described, has produced a detailed but very readable work. While it is no ready-reference book for house-surgeons, it will certainly appeal to the young surgeon who wants to base his treatment on up-to-date information. In the excellent chapter on postoperative complications, special care has been taken with the section on thrombosis and thrombophlebitis and the results of treatment with heparin and dicoumarol. Lung complications are also well described: but the six pages on postoperative retention of urine might be quoted as an example of over-enthusiastic thoroughness. Transfusion receives due attention, and the complications introduced by the Rh factor are well explained. The figures quoted as the *average* blood-loss in common surgical procedures—594 ml. in biliary-tract operations, and 808 ml. in radical breast amputations—are surely higher than even the most meticulous honesty could enjoin.

Prof. Jacob Fine covers a rather wider field in shorter compass. His introductory chapter on surgical diagnosis contains just those pearls of wisdom which will endear him to the young houseman. This book is essentially practical, and less theoretical than that of Ilgenfritz, though the physiological issues are covered quite clearly. The house-surgeon will find in it just the sorts of information he is always needing—for instance, a table of blood-chemistry tests and their normal values—and by such neat devices, enticing him on to read the text, it will educate him in surgical therapeutics.

Ilgenfritz, while very fairly discussing the advantages of early ambulation, leaves the final impression that it is just a little cranky, and the old way is best. Fine, on the other hand, has no hesitation in recommending that the adult patient should be out of bed the day after operation " regardless of age." Ilgenfritz, even if he allows his patient to get up, forbids him to sit in a chair; Fine has no objection to his sitting. Ilgenfritz relies a great deal on postoperative narcosis, and advises three-hourly narcotics to be given for two days after operation; Fine, in an excellent section on pain and sedation, forbids the administration of morphine for restlessness or apprehension.

Professor Ilgenfritz's book will appeal to the surgeon whose aim is to understand thoroughly the physiological basis of surgical therapeutics; Professor Fine's to the practical and inquiring mind whose concern is with the immediate clinical problem.

Diagnosis of Viral and Rickettsial Infections

Editor: FRANK L. HORSFALL, jun. A symposium held at the New York Academy of Medicine, Jan. 29 and 30, 1948. New York: Columbia University Press. London: Oxford University Press. 1949. Pp. 153. 21*s*.

THIS book comes close on the heels of another American publication, *Diagnostic Procedures for Virus and Rickettsial Diseases*, which appeared only a year ago and is also the work of a panel of experts. Comparison of the two books is inevitable. They are of a similar size (though not thickness) and could easily be mistaken one for the other. The earlier book, edited by T. Francis, jun., is rather more than twice as long as this one and covers a greater number of diseases; the prices are similar. In both volumes G. Rake has dealt with lymphogranuloma venereum, G. K. Hirst with influenza, and H. N. Johnson with rabies; otherwise the contributors are different. The earlier book gave very full accounts of the diagnostic procedures concerned and was therefore largely designed for experts: the Horsfall volume, on the other hand, describes the techniques more succinctly and readably and is directed rather to enlightening the student and the practitioner as to their uses and limitations. The practical value of the book is lessened by an extraordinary omission: in Great Britain the virus disease most urgently demanding laboratory help in diagnosis is variola; and for that we look in vain. Yellow fever too is omitted, though other tropical or exotic infections find a place.

Biometrical Genetics

K. MATHER, D.SC., PH.D., F.R.S., professor of genetics, University of Birmingham. London: Methuen. 1949. Pp. 162. 18*s*.

HOW to reconcile our knowledge of the behaviour of segregating hereditary traits with the genetics of characters showing continuous variation has perplexed many people. Mendel and Bateson exclusively studied segregating traits; Galton and Pearson, on the other hand, studied mainly the genetics of continuously variable characters like stature, head-shape, and intelligence. It is now generally believed that the genetical background of these and other continuous metrical characters is multifactorial; that is to say, they result from the cumulative actions of many genes, most of which have small effects on the particular measurements concerned. Professor Mather postulates that, besides the ordinary genes for segregating characters (major genes), there are also special genes responsible for continuous variation (polygenes). These polygenes have small additive effects and are assumed for the most part to be located in the heterochromatin of the chromosomes, which has usually been thought to be inert. Armed with this hypothesis, Professor Mather proceeds skilfully to analyse the results of some breeding experiments in plants and flies and to estimate how much of the variation in certain traits is due to genetical factors and how much is due to environment. The disturbances due to dominance of some genes over others and to linkage are ingeniously disentangled, though the phenomena of sex-linkage are not dealt with.

In human genetics, non-segregating traits are extremely important both in physical anthropology and in medicine. Susceptibility to disease, on account of diathesis or hereditary constitution, usually shows continuous variation, and probably can only be analysed genetically on a multifactorial basis. Professor Mather's demonstration of what can be done in randomly breeding systems, to which human populations approximate, follows with some amplifications the lines laid down by Fisher. The limitations of such methods in man, where environment is never homogeneous and mating hardly ever at random, are mentioned. Many readers may find th disagreeing with the author's assumptions nature of polygenes, and others will find the the subject too formal for their taste. His work however, stimulate further investigation of the of human metrical traits, which have been neglected in recent years.

Psycho-analysis

(2nd ed.) EDWARD GLOVER, M.D. London Press. 1949. Pp. 367. 15*s*.

THIS is a good deal more than a second edition epitome that appeared in 1939: it is now three times as long, and has a lengthy added cha "psychosomatic and allied disorders." The though more elaborate, exhibits the same vigour as before. Dr. Glover's well-known to the deviations from Freudian theory deve Mrs. Klein are discernible enough, but the tone book is not controversial. Doctors, social work students of comparative psychology, for whom is intended, will find it a well-organised, unco account of the theory of psycho-analysis which in this country until comparatively recently and still widely accepted among psycho-analysts

Die Primäre Tuberkulose bei Erwachsenen Kindern und ihre Entwicklung

Dr. Med. ST. J. LEITNER, Privatdozent für Medizin, der Universität Bern. Berne: Huber Pp. 157. Sw. fr. 15.

Dr. Leitner recognises three stages in the our knowledge, between the two world wars, progress of pulmonary tuberculosis. In the of this century the old view of the gradual an initial apical lesion still prevailed. Then, the result of the rapid improvement in X-ray te there followed the concept of a relatively acute the disease with an early infiltration (*Fr* the subapical region of the lung. Lastly the recognises as a third phase, beginning about concept of an early hæmatogenous apical spread a primary lesion elsewhere. With this new mind, and on the basis of an experience gained series of 266 cases examined in the University Berne, he has written an instructive account of tuberculosis and its development both in the in the adult.

The patients were followed up for 2–8 years their first admission to hospital. Complications and late, are recorded, and the results up to given. Dr. Leitner is impressed with the tuberculosis so often presents itself as an acute such as influenza or pneumonia, and from acute phase, with its tuberculin sensitivity, blood picture, and characteristic X-ray traces the disease through the stages of nodosum, pleural effusion, and the other post- stages, to the early hæmatogenous apical lesion insists that observation in hospital should not when the clinical manifestations of this acute subside and the blood picture returns to norm should be continued until radiography shows improvement, when the patient can be referred to the outpatient clinic. The value of sanatorium trea for the early lung lesion does not, in his opinion, of any doubt; and the claim for hospital trea other forms of the disease is, he believes, equally for though it will not always prevent the early togenous spread, it often will do so, and is the important safeguard. His experience of strepto treatment justifies some optimism.

Throughout the book he drives home the that observation must be continuous until healing place—too often a counsel of perfection in these bed scarcity. But readers will share his belief is an end to be kept constantly in mind.

The Proceedings of the International Congr Mental Health, 1948 (London: H. K. Lewis. 1949. Pp. 50*s*.), have appeared in four convenient paper volumes. Those who wish to refresh their memory was said during the congress by opening speakers discussion will welcome this full and careful compila

For Coughs following "Colds," etc.

'BENYLIN'
Expectorant

The ability of 'Benadryl' to relieve the cough and other distressing symptoms associated with the "common cold" represents still another clinical application of this remarkably versatile drug. The value of 'Benadryl' in controlling these symptoms is connected with its antispasmodic and broncho-dilator properties.

In 'Benylin' Expectorant, 'Benadryl' is combined with proved expectorants in a raspberry-flavoured syrup, which is readily acceptable to both children and adults.
'Benylin' Expectorant not only relieves coughs, but is also effective in alleviating nasal stuffiness, sneezing, lachrymation and bronchial congestion.

Each fluid ounce contains :

'Benadryl'	80 mgm.
Ammonium chloride	12 grs.
Sodium citrate	5 grs.
Chloroform	2 grs.
Menthol	1/10 gr.

Dosage :—Adults : 1–2 teaspoonfuls. Children : ½–1 teaspoonful.
In 4, 16 and 18 fl. oz. bottles.

Research

hould not be misled by the fact that the earch' has now become a slogan to secure d private funds for activities sometimes ectable than fruitful." So says the president ockefeller Foundation.¹ What then do we research? PAUL FREEDMAN has made a tempt to answer this question, and anyone in research will find much stimulating n his small book, *The Principles of Scientific* FREEDMAN has had a long career in electrical research, and much of what he ugh applicable to physical research, cannot d in medical—especially clinical—research; hould like to quote some of his ideas and how they apply in the medical field.

ok begins with the history and philosophy ific research, and this differs notably from ry of science as a whole. Then follows a n the mental approach. "One of the greatest s between scientific and non-scientific men- he says, "is the care taken to avoid ted assumptions and baseless inferences." goes on to divide scientists into two groups: r, who accept all previous knowledge, and smaller group who recognise that existing knowledge is not completely valid or per- y true; it is only in the latter group that the ntists are found. This is not, of course, an itation to ignore all preceding work; you ppraise previous work unless you know about problem is how to acquire the necessary ge without having one's mind "set" in the This problem certainly arises in medical , and the trouble is that, unless they have science degree at their university, doctors d little training in the assessment of evidence drawing of conclusions at the level needed arch. This defect in training is responsible kness in what FREEDMAN calls "finalising" ch—i.e., knowing when the time is ripe for g the material and results and drawing ions or proposing a hypothesis.

> atience and thoroughness without ability to e can produce only an endless accumulation of which remain dormant. . . . Ability to finalise, ut the capacity for patient and thorough work, give at best a succession of brilliant ideas that unless they succeed in inspiring a more solid tigator; they are like flowers without roots."

les of both these faults can be found in most rs of specialist medical journals. FREEDMAN set out methodically the points of the correct approach to research problems. In medicine, ts very variable material, we cannot help g that a less systematised approach is better; dding medical researcher may well learn more from SINCLAIR LEWIS's *Martin Arrowsmith* than from FREEDMAN's rules.

Then there is the question of singleness of purpose and avoidance of frittering away time and resources on other understandably tempting activities.

> "It is not an accident that so many scientists engaged on research appear to develop blinkers which shut out so much that is worth seeing; not an accident that the wives and families of so many pioneers lived through years of poverty; not an accident that so many promising young scientists abandon the research they love, 'temporarily,' to earn more in other branches of activity where science is better paid, only to find that when at last their resources have become adequate nothing can give back the vanished years. It would be an impertinence to suggest to young scientists devoted to research what sacrifices they should make. But it is the act of a friend to tell them that, in this country at any rate, they may have to face the need to make sacrifices and may have to ask themselves whether these are worth while."

This is certainly true in medicine. The pure laboratory worker can devote himself single-mindedly to the inquiry in hand, but the clinical worker has always to consider the claims of his patient as well—and these often conflict with the research programme. The advent of the National Health Service has exaggerated another liability of medical research-workers, particularly departmental heads—attendance at committees. Professors of clinical subjects seem to be automatic choices for regional boards and similar bodies; yet, as WITTS has pointed out, if they are to fulfil properly their obligations to teaching and research they should not be spending time in this way when others, without their special responsibilities, are available. In addition to teaching and research, care of patients, and committee attendances, some undertake private practice as well. It is not surprising that few can do systematic research under such conditions; in any generation there are few men like JOHN HUNTER —and he succumbed to coronary occlusion. Then again, how can we hope to attract the right men into research when an adequately paid career in the National Health Service seems to depend so much on ascending the ladder by the prescribed route, and when better pay is offered at the higher grades —paradoxically better for part-time than whole-time work—than can be hoped for in a research career? The recent increases in the salaries of university teachers have gone some way to redress the balance, but the gap is still large enough to demand serious sacrifices, and this is particularly true of research grants and fellowships.

FREEDMAN's chapters on the planning and organisation of research are naturally taken from the field he knows; medical work can rarely be planned in such detail. He has much to say about team-work and about desirable and undesirable kinds of teams. He gives an amusing example of the "political" and the "Socratic" method of dealing with the earnest junior who thinks he has discovered an error in accepted teaching. He is not afraid to tackle the thorny question of giving credit where credit is due. BERNAL has said: "Perhaps the most convenient chiefs are those amiable scoundrels who establish a kind of symbiosis with their research-workers, choose good ones with care, see that they are well supplied with apparatus, attach their own names to all their papers, and when at last they are found out, generally

ard, C. I. Rockefeller Foundation, New York. Annual port for 1948; p. 10.

lman, P. The Principles of Scientific Research. London: cDonald. 1949. Pp. 222. 15s.

logical complications to an operation which is already difficult enough. Moreover, material for a graft will not as a rule be available unless it has been stored, awaiting use, for some days or weeks beforehand. PEIRCE and his colleagues,[1] after recalling and appraising the great variety of storage methods hitherto tried, now suggest that the best results from vascular transplantation are to be expected from grafts which have been stored in the viable state. Their test of viability is to cultivate fragments of stored vessel in an adequate nutrient medium containing embryonic extract. The outgrowth of fibroblast cells and possibly of fibroblast-like endothelial cells from the explants, combined with orthodox histological examination, gives acceptable evidence of the grafts' well-being. The method of choice, they believe, is to store vessel segments not less than 1 cm. long in a 10% solution of homologous serum in a balanced and buffered salt solution containing sufficient penicillin and streptomycin to bring each to a final concentration of 50 units per ml. The temperature of storage, which apparently is not critical, should lie a little above freezing point, and the storage vessel, a simple conical flask, should be tightly stoppered. Viability is preserved for as long as seven weeks, and during the first three weeks the vigour of outgrowth from the test cultures may even exceed that from the control fresh material. These workers find that storage in diluted serum is superior to storage in plain salt solution or neat serum, or to storage in the frozen state after quick freezing.

Whether foreign grafts are acceptable remains as uncertain as before. In four trials of each, the same workers[2] grafted pig and baboon or human vessel segments into defects made in the abdominal aortas of dogs. One of the grafts of pig origin was functional after 30 days, and another after $4^1/_2$ months; the rest were more or less thorough failures. The conclusion arrived at is that the use of such heterografts might be practicable in some combinations between donor and recipient but not in others. The results were much more favourable with homologous grafts after varying periods of storage. Sixteen homologous grafts in dogs, with material which after storage for 1–70 days had been left in situ for two months or longer, gave results classifiable from a qualified "good" to a bald "excellent." Stored human vessel segments were then tried in nine children, eight of whom had a cyanotic type of congenital heart-disease; the grafts were used to shunt blood from the aorta or one of its branches into the pulmonary artery. A considerable fall of the red-cell count combined with improved exercise-tolerance was recorded in five cases after follow-up periods of 2–5 months; one patient did not improve; and two died, on the 2nd and 15th days after operation, though the vessel operation was not directly implicated. PEIRCE and his colleagues are already engaged on a fuller clinical trial.

A less encouraging experimental report has been published by WILLIAMSON and MANN.[3] They exchanged both arterial and venous transplants between the members of three pairs of dogs, each dog receiving one arterial and one venous graft of logous origin. Six venous grafts and four grafts were found to be non-functional when 56–62 days after operation; one arterial graft a functional state, and one other partly They conclude that, whereas autogenous tion of vessel segments is feasible, homologo *plantation is not yet justified.* The contradictory reports of these two types some variable other than a purely immunolo must govern the fate of homologous vessel The graft is mechanically most vulnerable the inflammatory process associated with the to foreign grafts is most intense—at the where native and foreign tissues unite. The of grafts may delay the onset of the reaction provoked by them (possibly by slowing vascular invasion) until union at the suture secure.

Annotations

POLIOMYELITIS AND TONSI

THE St. Pancras coroner has lately investig death of two young brothers, aged 7 and 4 years developed polioencephalitis soon after their tons removed. Tonsillectomy was performed on Aug. 5 child fell ill on the 18th and the other on the the inquest a medical witness cited the warning by medical officers of the Ministry of Health in when the incidence of poliomyelitis was high,[1] that is "overwhelming evidence that a recent t increases the risk of a child contracting p particularly of the bulbar type; where p prevalent operations on the nose and throat s possible, be postponed."

Not everyone holds with this advice. At the meeting of the British Medical Association last view seemed to be that the risk, if it existed, was n as to call for prohibition of the operation.[2] Dr. McFarlan, however, said that recent tonsill increased the danger of the disease assuming the form, and asserted that during epidemics abstenti the operation might eliminate some of these severe though it might not reduce the risk of clinical i with the virus. And Dr. Stanley Banks[3] claimed the prohibition of tonsillectomy was the only preventive measure.

The facts pointing to enhanced risk from ton have been marshalled by Glover,[4] whose experience in North America suggests that tonsillec (recent and possibly remote) very probably incre risk of clinical infection with the virus, and th certainly increases the risk of the dangerous bulbar Glover quotes, among others, Anderson's[5] review [illegible], where it appeared that [illegible] had an attack-rate more $2^1/_2$ times greater, and a chance of getting the type 16 times greater, than other children.

In relating such reports as this to the death of the London boys, it has to be borne in mind that this outbreak has been characterised by an unusual numb multiple cases in families[6]; and the coroner re attribute the two deaths directly to tonsillect Nevertheless this tragic incident may increa ice to operate when poliomyelitis is abroad: and etter on another page Mr. T. B. Layton comes :rongly on the side of waiting until the disease is er prevalent.

CASUALTY WAITING TIMES

ıe busy casualty officer diving from case to case e spent by patients in waiting for his attentions ke the twinkling of an eye; to the sick or injured sitting on a bench, any delay seems interminable. ive judgments, however, are out of place when a can be measured by the clock. Mr. Patrick n, F.R.C.S., has found out exactly how long s spend in the "front surgery" of Guy's Hospital raiting for examination, primary treatment, and l.[1] The general impression of the medical and staff was that most people spent less than two n the surgery, and that if a patient spent more ur hours there it was due to something avoidable. ours, at first blush, seems a good long time for or injured person to sit, or even lie, about; four altogether too long. Yet analysis shows that not squandered by the examining officers.

rding to established routine the patients (unless re ambulance cases) enter and sit in the hall. ırse sorts them into the sick and the injured, their temperatures, and enters the personal lars of each patient in the surgery book and on , which she gives to him. He then waits until een by a dresser who takes his history, examines ests his urine, and takes his blood-pressure. Half tients were seen by a dresser within ten minutes ving in the surgery, and 80–90% within half an The dresser, having examined his patient calls patient officer (O.P.O.) who also examines him, and ssary fills in a form for the X-ray department. ver 60% of patients were seen by the O.P.O. within minutes of arrival, and 70% within forty minutes. iography is needed the patient then walks, or is , to the X-ray department; and when the film een taken returns to the surgery to wait for its y and examination, by the O.P.O. The time spent X-ray department proved to be uniformly short: er 80% of patients the X-ray examination was ete within ten to thirty minutes of reaching the ment; less than 5% spent fifty minutes there, one over seventy; and this included cases, by no uncommon, of multiple injuries requiring several of skull and spine which could not be taken in less orty-five to fifty minutes. Allowing for the time by the patient in getting to the X-ray department o fifteen minutes) and the time required for the of the films and their examination by the O.P.O., 0% of patients radiographically examined spent tra hour in the surgery; and no great reduction average time, Mr. Clarkson thinks, can be expected ut sacrifice of proper care. Once the diagnosis is l, treatment—which, in the case say, of a hand , may include a twenty-minute toilet of the wound, full-dress repair in the theatre under anæsthesia— s, and after this the patient goes to the injection for antitetanic serum and penicillin. If he is go home he then returns to the desk for his card to mpleted; if not he may wait to be admitted or sent elsewhere. Those needing a hospital bed apt to wait longest: 5 cases (0·3%) out of 1500 ed waited over five hours on this account; but no they waited in comfort in the rest and observa- oom. Only 103 (7%) spent more than three hours e surgery, and most of these were patients who ed prolonged observation.

e analysis shows clearly enough that from the ors' point of view no time is wasted: every stage of the admission and examination procedure has its purpose and is designed for the ultimate benefit of the patient. On the other hand, upwards of two to three hours spent on a hard chair or bench in a draughty admission hall, alongside an outer door in constant and noisy use, must seem long to a patient with an aching head, a lacerated hand, or a crushed foot. What is needed, at Guy's as elsewhere, surely, is a comfortable casualty waiting-room, furnished perhaps with tubular deck-chairs, and tubular-and-canvas arm-rests and leg-rests, and certainly (like the torture chamber in *The Gondoliers*) with all the illustrated papers.

DISEASE FROM DOMESTIC ANIMALS

BOTH cats and dogs, though more resistant than man, are susceptible to tuberculosis. Cats are mainly affected by the bovine type of tubercle bacillus, probably derived from raw milk, whereas dogs are more commonly infected by the human type. With "open" lesions of the lung, intestine, or skin, large numbers of bacilli may be disseminated. Speaking at the annual Veterinary Congress last month, Dr. J. Winsser, of Leyden, remarked that in Holland, as in Britain, small domestic animals commonly live in close contact with adults and children; sometimes they sleep in their owners' beds and even receive food from their lips. Dr. Winsser himself developed a tuberculous ulcer of the finger, due apparently to infection from a dog; and dogs and cats have been found at necropsy to be suffering from the same type of tuberculosis as patients in the owners' families. In most of the bovine-type cases, however, a common source of infection seems the most likely explanation, and where the human type is implicated the disease is probably transmitted from man to animal.

Leptospirosis, especially the variety caused by *Leptospira canicola*, is very common in dogs; in Britain surveys have revealed evidence of past infection in up to 40%.[1] When they become infected many of these animals show no symptoms of disease but become healthy carriers; the leptospiræ establish themselves in the kidney tubules, and are shed in the urine; finally the organisms die out, but for some months the dog is a source of danger to other dogs and to man. Cases of canicola fever are now being recognised more often in this and other countries. In its early stages the disease often resembles poliomyelitis, and the possibility that the two conditions may be confused has lately been discussed in these columns.[2] An interesting report[3] from Holland describes how a laboratory worker became infected with *L. ballum*—a species hitherto found only in its carrier host, a field-mouse (*Mus spicilegus*). Investigation showed that a high proportion of healthy, tame white mice from certain dealers were excreting this organism, though other stocks were completely free. Of late years salmonellosis has been diagnosed in a number of cases of enteritis among dogs, and to a lesser extent among cats. *Salmonella typhi-murium* is the organism most often isolated, but Winsser lists over twenty other salmonella types which have also been found. Only rarely, however, has food-poisoning in man been traced back to infections in dogs. The danger of contracting psittacosis from imported psittacine birds has been eliminated almost completely by appropriate regulations, but a closely related virus which is carried by pigeons is known in England and some other countries and has recently been isolated by Dr. Winsser in Holland. Complement-fixation tests indicate that in the Netherlands this "ornithosis" virus is widespread among pigeons, especially the homing varieties. Though less virulent for mice and men than

true psittacosis, it has caused pneumonia in pigeon-fanciers and their families. Fungal infections of the skin are very common in animals, and many are readily communicated to man, producing ringworm of the naked skin. The lesions are easily and rapidly cured, and the condition should perhaps be looked on as a minor inconvenience rather than a disease. Winsser notes the possibility of transmission of streptococci, *Tænia echinococcus*, and toxoplasms from dog to man. Mention should also be made of the rôle of dogs as reservoirs of *Leishmania infantum*, the cause of infantile kala-azar along the Mediterranean littoral, and of *Trypanosoma cruzi* which produces Chagas's disease in South America. But his most unexpected omission is rabies. In time past, and even now in many countries, this disease would be given pride of place as the most dangerous member of this group.

It appears that rabies and psittacosis are the two diseases communicated to man from household pets that can constitute a grave risk to life. In Britain at least, regulations have been framed and administered so successfully that the risk of these infections is now negligible. This central legislative action has been effective because the general public appreciates its value, and, with a few exceptions after the first world war, has not tried to evade its application. Infantile kala-azar, Chagas's disease, canicola fever, and food-poisoning provide public-health problems of a different type, and they can probably best be handled at the periphery—by close liaison between veterinary and medical practitioners. Thus, while our pets may from time to time unwittingly cause us hurt, they cannot be accused of conspiring to destroy us.

CURARE IN SPONDYLITIS

In rheumatoid arthritis and the allied condition of ankylosing spondylitis the pain gives rise to a reflex protective muscle spasm, and this in turn, though it *splints the affected joint or segment of the spinal column* more or less effectively, also produces a good deal of pain and stiffness. A self-perpetuating circle is set up, and the reflex arc concerned develops a lowered threshold which means that normally minimal sensory stimuli will excite further spasm. It was natural that the introduction of curare and allied drugs into clinical practice would lead to attempts to interrupt this circle, and earlier reports on *d*-tubocurarine for the spasticity of cord injuries and other conditions have been given by Schlesinger.[1] Schlesinger used an oil-wax suspension of the drug to produce a continued relaxing action, and now Norcross and others [2] describe results with a similar *preparation in ankylosing spondylitis.* They gave a 3% suspension of *d*-tubocurarine chloride in a mixture of wax and peanut oil, starting with a small dose at intervals of 24 hours or less and finally establishing an optimum maintenance dose given every 72–96 hours, which was just enough to abolish clinical evidence of spasm. In spite of the potential dangers of setting up a body depot of more than twice the therapeutic dose, they did not experience any major toxic manifestations, though it is necessary to be prepared to deal with these. Minor troubles—diplopia, myasthenia, or dysphagia—respond at once to neostigmine, but major respiratory distress might well require tracheal intubation or even artificial respiration. The 6 cases treated benefited considerably. Electromyography demonstrated a lessening of motor-unit activity; pain and spasm were reduced or relieved, movements improved, and spinal deformity partly corrected.

It is difficult at the moment to assess the p
indications for such treatment, other than as an ad
when other therapy has failed, but it would be a
the rather remote prospect of greater supp
cortisone [3] damped enthusiasm for further resear
this field. Clinical practice in this country with
drugs, such as mephenesin ('Myanesin') confirms tha
have some value in Still's disease and rheumatoid ar
generally, and more work on these lines seems
required.

ESTIMATION OF STREPTOMYCIN SENSITIV

In estimating the streptomycin sensitivity of a
of tubercle bacilli infected material is first ca
on solid medium and the organism then grown
liquid Tween-albumen medium of Dubos and
If a nongranular inoculum can be obtained i
way it is sown into a series of tubes of the liquid m
containing varying concentrations of strepto
and the sensitivity of the strain can be reported
later. The test takes about 2 months—a long w
a laboratory report even in such a chronic dis
tuberculosis. Another disadvantage is that
resistant mutants may flourish in the liquid m
containing streptomycin and thus mask the real
tivity of the mass of the infecting organisms. To
come these *difficulties Holt and Cruickshank*
added streptomycin, in suitable concentratio
tubes of the medium used for primary isolation
bacilli. Streptomycin may be added before o
sterilising the medium but the potency of the an
is reduced by about a third on heating. Specim
sputum from 68 hospital patients, none of whom h
streptomycin, were homogenised by the Jun
technique and inoculated on one tube each of Lowe

oes have been given what was considered to be ical inoculum. This usually happens when the e scanty; it may occur when they are numerous. ı found that viscous sputum could best be ised with a few drops of normal sodium hydroxide n submitted to acid digestion. Whether this is as satisfactory as the Jungmann technique fying sputum it is difficult to know but it is emember that all such methods probably have a ect on the tubercle bacillus.

er rapid method [6] of performing sensitivity tests ubercle bacillus is to use a modification of the ture technique of Pryce. Material is smeared surface of slides which are then immersed in lbumen medium containing varying concentra- streptomycin. After incubation at 37°C for stained smears are compared with samples without streptomycin. This method may be ith pure cultures or with heavily infected material ot likely to help when there are few bacilli in the material.

hever method is used it is necessary, as the n Trudeau Society insists, to isolate and study of the infecting strain before a patient is subjected tomycin therapy. Halving the time taken for ity tests should help to foster this collaboration ward and bench worker.

THE MENTAL HOSPITALS

Minister has disclaimed only five mental hos- Manchester Royal Hospital; Cheadle, Cheshire: od House, Gloucester; St. Andrew's Hospital, mpton; and the Retreat, York. Bethlem Royal the Maudsley Hospital in July, 1948, to form a nit which is designated as a teaching hospital; lical school forms the institute of psychiatry in tish Postgraduate Medical Federation of London sity.

eir report [7] for 1948 the Board of Control note he number of patients under care remained ably steady: 144,725 in 1948, compared with in 1947. Some 97% of these were in hospitals in the Minister of Health. Last year the board d [8] that at the end of 1947 the number of patients ic wards overcrowded "on the basis of recognised rds" was 14,668, compared with 16,662 at the 1946. This year the figure has evidently risen, y state that the overcrowding in former county rough mental hospitals at the end of 1948 was compared with 11·7% at the end of 1947. Over- ng is still attributed to lack of beds and staff, and ard report that at the end of 1948 the Mental . Service was still denied the use of 3034 beds, lly diverted to the E.M.S. or Service Departments r-time purposes, and not yet returned. Moreover, eds are not in use because of the scarcity of , and 2694 beds are "in process of reinstatement." ill staff be available when they have been ted?

year the board made the encouraging announce- hat, in 1947, 54·5% of the total of 39,223 admis- were of voluntary patients. It is not possible to te from the figures given this year what the tage of voluntary admissions was in 1948: it vell be lower. The figures given throughout the are somewhat scanty. This is probably due, as ard explain, to "the absence of detailed information movement of persons suffering from mental er in former public-assistance institutions and public-health general hospitals now designated as mental hospitals, and in premises not vested in the Minister of Health but deemed to be mental hospitals." The year under review was one of great changes, and no doubt the board were working under difficulties: nevertheless the medical profession and the public need to have a full and clear idea of what is happening in the mental hospital service, and would welcome a much more detailed account next year. Overcrowding deserves particular consideration, for it can aggravate existing mental illness and hinder recovery. For this particular evil the pleasant social activities described here—music therapy, art classes, whist drives, concerts, and other entertainments or occupations—are no remedy.

The board note that medical certificates of insanity are often inaccurately or incorrectly filled in—just as they were when the Commissioners of Lunacy reported to the Lord Chancellor in 1846. A study, made in 1948, of 6156 admission papers of temporary and certified patients led to 384 being returned for amendment on medical grounds and 1291 for amendment for technical reasons—not a very reassuring finding for the mentally sick and their friends.

THE KING'S FUND

"Menus for patients on light or special diets are seldom planned," the fifty-second annual report [1] of King Edward's Hospital Fund for London notes in a section on hospital catering. Those on light diet get an unchanging midday meal of steamed fish, mashed potatoes, and milk-pudding. No cooked dish is provided for their supper, and the diet must often be inadequate as well as monotonous. As the report points out, patients on light diet need highly nutritious meals rich in protein to build them up. One meal a day, and that untempting, will never do it. The catering in many hospitals, the fund's visitors find, still fails to meet the nutritional needs of patients, and this failure is usually the result of an old-fashioned system. The responsibility for catering is often divided between the matron and the steward, the matron being responsible for staff menus, cooking for patients and staff, service to staff and to patients once the food has reached the wards, and kitchen staffing; and the steward for the patients' dietary (using standard menus prepared by a committee), transport of food to the wards, all buying, and stores. The result is that staff meals are planned more carefully than patients' meals, and there is little opportunity for anybody to introduce new dishes into the wards.

The King's Fund have long held that catering should be a hospital department in the hands of a single experienced officer. The chef too should be experienced, and should be paid at rates similar to those he would receive in hotel or restaurant. The advice of dietitians should be available, and the equipment for taking the food to the wards adequate. The fund, who have said all this many times in many different ways, encourage progress by means of a dietetic advisory service. Many London hospitals have appointed catering officers, on whose initiative the Hospital Caterers' Association has been formed with Sir Jack Drummond, F.R.S., as president. Since trained caterers and cooks are scarce the fund is about to found a training centre at St. Pancras Hospital, now part of University College Hospital. It will be built on a bombed site, and is to offer a model of layout and equipment. In time it will turn out cooks and caterers in plenty. This fits in aptly with a new Ministry of Health circular [2] urging better training of hospital cooks. The Ministry recommend two courses

provided by the City and Guilds of London Institute as being "most nearly applicable to hospital work." The King's Fund course will doubtless be planned directly for hospital purposes.

The committees of the fund are in the almost unique position of having more money to spare than usual. State responsibility for the maintenance of hospitals has freed the fund from many financial commitments, and given them the use of their money for other purposes. One new departure is to provide and expand ancillary services to relieve hospitals, such as homes for the aged sick. The experience of their Emergency Bed Service—which last year could not find beds for some 3500 patients, most of them over 60—has impressed the fund with the urgency of this need, and they are helping voluntary bodies to provide homes with nursing facilities for such patients. They are also willing to subsidise bodies who will set up homes linked with hospitals, to which old patients can be transferred when they no longer need active treatment. Even in old age we feel the need of incentives; "to get well enough to go to the home" might, if the home is good, prove a stimulating ambition for bed-ridden grandparents.

Many other undertakings are recorded in the fund's report. Convalescent homes are being helped financially and encouraged to raise their standards; the Nursing Recruitment Service continues to do much rewarding work; the staff college founded to prepare newly appointed ward sisters for their duties is now in full swing; and the fund offer scholarships to nurses to travel abroad, training grants to almoners, and training schemes for administrators and medical records officers. Hospital accounting, now under such keen discussion, has long been among their foremost studies and they are pressing cogently for the adoption of a departmental system of accountancy.

MORTALITY IN EUROPE

THE career of the chief of the health statistics section of W.H.O., Dr. M. Pascua, has given him a breadth of experience of the vital statistical systems of Europe second to none; for that reason his introductory comment on its snares and delusions adds much to his recent report[1] on international comparisons of mortality experience in Europe. Much depends, for example, on the efficiency of death registration; under-reporting of deaths, particularly in infancy, is, or was, common in some countries. National differences in definition may cause appreciable differences in mortality-rates; thus what might have been termed a stillbirth in one country would have been classified as a neonatal death in another, with the net result of an increase in the over-all death-rate in the second instance. Pascua is a little dismayed by the failure of the death-rates given in national publications to tally with those calculated independently from the data about deaths and population given in the same publication. Shifts in population, selective migration, and changes in age-structure following new trends in the birth-rate all tend to distort the picture. Despite his own depressing catalogue of imperfections, Pascua believes that good use can be made of such data, and this, the first of a series of such articles, lends substance to his plea.

The main emphasis of his review is on the relative declines in total mortality which have taken place in many European countries. Generally speaking, there has been a steady fall in the death-rate in all the countries surveyed, and this fall, though checked by the two world wars and the 1918 influenza pandemic, has gone on to allow the recent achievement of record low levels of mortality. Indeed the Netherlands rate of 74 is a historical world record. Of fifteen countr a crude death-rate of more than 15 per thou annum at the beginning of the century, not o death-rate above this level in 1947, only two ye the end of world war II. The rate of fall, of co not been consistent in pattern in all these States steepest in Spain, Italy, and the Netherlands, the Scandinavian countries and Switzerland, so in the British Isles, Belgium, and France. Mo reduction in mortality has taken place in the d infancy and childhood; little, if any, progres made among the killing illnesses of middle and Yet without such advances the present rate of ment in total mortality must slow down, for, around 1900 only 7·5% of the English and Wel lation were aged 60 years and over, by the en this proportion had risen to 15·2%.

All these changes in mortality experience a ably reflected in an increase in the "expectatio (in its actuarial sense of how many years a likely to live if the age-sex specific death-rate at a specific period continue to prevail). In Sp 1910, the "expectation of life" at birth was years. That did not mean that a Spaniard born was likely to live 41 years; the expression is useful way of summarising the mortality expe Spain in 1910. What are termed "generati tables have been constructed by applying to a "cohort," born in, say, 1880, the age-sex speci rates which would have prevailed during thei —e.g., for the first years of the table, the death children aged 1, 2, 3, 4, or 5 years in 1881, 18 &c. From the life table thus obtained for peopl 1880, the "expectation of life" does summ conditions prevailing during their lifetime an nearer to the lay conception of the meaning of t than does the usual form. Some interesting such "generation" life-table construction are for men born in England in 1840, for example, t tation of life on this basis was 39·5 years; for t in 1860 it was 42·8. But for most purposes th tional usage, which summarises mortality at on time, is a more useable index of public healt moment. Progress, or lack of it, can thus be con measured in terms of changes in the expectatio Compared with 1910, the expectation of life in S increased by 9 years to 49·8 years by 1930 similar, if less striking, advances were made by countries. In 1930, considerable differences bet fifteen countries still persisted. The northern la Sweden in particular with an expectation of lif years for men at birth—contrast vividly with I Spain with their expectations of 53·8 and 49 increasing age, however, this disparity decreas at about age 60 the differences are much sm they disappear altogether at 70. It is in infa childhood that the northern countries gain thei tage. With the remarkable consistency which terises these data, the same phenomenon appear the tables of the expectation of life for *females* in life these show a superiority of two years over t of the same nation, but with advancing years parity gradually decreases until it is not much m a year at age 60. Thus again we see how large bution the fall in infant and child deaths has the trends in Europe's crude death-rates since of the century.

Mr. DUNCAN FITZWILLIAMS has been appointed of the Society of Apothecaries in succession E. C. Dodds, F.R.S.

Disabilities

38. TRANSVERSE MYELITIS

than nineteen years have passed since my paralysis. It began on the thirty-third day of nia, from which after being seriously ill I had so as to be looking forward to an early ence at the seaside.

orning, as I lay in bed, I felt an ache in the was troublesome from the onset, got steadily ring the day, and by evening had become a n, surging in waves round my waist. I was pass water. In the evening my buttocks næsthetic, and after this both legs rapidly aralysed, the last movement to disappear being the big toes, which showed a well-marked response. I slept well under the influence of Next morning I awoke to find myself com- aralysed and insensitive below the waist and raise my shoulders from the bed.

ewed the situation, being fully aware of the ce of what had happened, and made up my ce and for all, to accept it without reserve, and no time in useless regret. This serenity of mind ssociated cheerful outlook survived through all les that were to come. It was interrupted only Vhen I was alone on a dreary February evening ater, a sudden consciousness of my utter help- came upon me, and I could have shrieked in steria. I turned my thoughts to something and the mood passed quickly. It recurred for ief moments two days later.

become very thin, so I had been put on a water- days before the onset of paralysis, for con- of nursing. After the onset I decided to live ges, about eight daily, as my sole nutriment. lays I was emaciated, little but skin and bone, ld my surgeon that at this rate I would die in s. He agreed, unless I took nourishment. my wife if she thought it worth while my con- to live if I remained paralysed. She unhesi- said "Yes," so I asked for Benger's Food and not to die of starvation.

* * *

e twelfth day a great event took place: a ished brain surgeon kindly came to see me ultation. He was an admirable consultant— s, full of understanding and kindness, and very -and I shall always revere his memory. Even- e gave me his verdict. "I have now got a e grasp of your case," he said. "It is very rare. not seen more than two like it. The lesion is all, no bigger than a split pea, about the level ninth or tenth dorsal vertebra, a little to the and posterior to your spinal canal. The rest of chief is collateral and recoverable. I have no at is to happen to you. I can only tell you that *absolute* reason why you should not ultimately almost completely, except for a slight weakness right leg." This wonderfully accurate clinical , given when I was still completely paralysed e waist, and expected to die at any moment, ed indelibly imprinted on my mind and was the of my faith and hope during the months that d.

days later I could move my big toes, and move- pread to my other toes, the ankle, knee, and hip, but continuous succession, until three months he onset, I got out of bed and walked in front of mantelpiece holding on by both hands. From the of the first month I had daily massage and ements. My weight had slowly increased.

With the return of movement came spasmod of the of my legs, especially in the evening and durin night. These were very disturbing and somet the violent. They were preceded by an aura, a sting in that region of the buttocks, very variable in site. Thu- threatened to interfere with sleep and I was fortunate er detect the chief exciting cause—hot feet and cool lege I found that if I once got off to sleep I could have a good night, though I seldom slept more than an hour at a time, being awakened by severe jerks. The night nurse would come in and turn me over on my other side, usually after cooling my legs, and I would fall sound asleep before she left the room. I usually was wide awake, sometimes for ten minutes, twelve times a night, but in spite of this enjoyed my night's rest and never had any hypnotics. I feel sure this was a factor in my recovery. After a few weeks the jerks began to diminish, but they persist to some extent to this day. I felt as if I were not lying flat in bed but on a slope, with my feet a foot or two higher than my head. This peculiar sensation lasted three years; slowly the slope became less; and I shall never forget my relief when at last I seemed to be lying flat once more.

* * *

My nurses were unremitting in their kindness and care, and I escaped without the suggestion of a bed-sore. I did not escape a severe urinary infection, with ropy pus. For some weeks I was catheterised, the bladder being rarely allowed to fill above 15 oz. When the use of the catheter was dropped I was found to have an automatic bladder with residual urine. The bladder was then washed out daily for a time, and the residual urine became gradually less; but as the urine did not become sterile either with washing out or medicine, both forms of treatment were soon omitted, and the bladder acted periodically and automatically. My bowels were the cause of much trouble. They were not constipated, spastic, or incontinent, but they did not act on their own: and after an aperient I had little control of them and an enema was unsuitable in the early stages.

A special piece of luck fell to my lot just before I got up, when I happened to read an advertisement of Hilliard's micturition bags.[1] I sent for one at once, found it ideal, and have worn one ever since. They are made of soft rubber and never chafe. They enable a man with an automatic or incontinent bladder to take his place (so far as that disability is concerned) as a normal member of society. The bag is unnoticeable in the ordinary way, but the wearer cannot safely sit on a low chair or the low seat of a motor-car.

My automatic bladder settled down to a maximum content of 4 oz. Three years later, during a single week, the maximum rose to 5 oz. Three years after that, again during a single week, it rose to 6 oz. There it has remained. It empties usually at 3–4 oz., leaving residual urine which can be almost entirely expelled by suprapubic pressure. If it decides to act when I am walking, the first indication is often a loss of power in my legs, slowing down my already slow pace, and indicating that either the lumbar centre cannot carry both loads (walking and micturition) or that there is an antagonism between the two mechanisms. At night the automatic bladder is much more difficult to manage. My method is my own invention. I lie on my side with the genital organs in a small kidney-dish, partly filled with cotton-wool. When I wake, if the bladder has acted, I empty the wet cotton-wool into a receptacle by the bedside and replace it with fresh. My bladder may act during sleep or may wake me. Once I fall asleep I do not change position unless I wake. I am always awakened three to ten times a night, but this has not interfered with my health. The problem of dealing with

ce of my de Morgan's spots, which reappeared
ter ; and an almost complete loss of the sense
d cold in both feet up to the ankles (even now
n bed I wish to know if my feet are cold, I have
them with my hands).

e day during my late convalescence I got a nasty
ht. I was standing on a Scottish moor *admiring* the
iew when suddenly I was laid *flat* on the ground as if I had been shot. This was clearly a dangerous thing to happen and I at once tried to find the cause and the remedy. Owing to the immobility, my right leg had given a sudden and violent jerk, and my left leg, caught completely off its guard, had simply collapsed. I have never stood stock-still since, but keep my legs moving imperceptibly. My locomotor troubles and my gait remain the chief and very obvious evidence of my illness. *My walking is never automatic but always reinforced by* a voluntary impulse, and I am always, so to speak, on guard, lest I stumble and fall. I used to pride myself on walking without a stick, but finding that it was a useless effort I have long used a light strong stick with a rubber tip, which enables me to walk more safely, quickly, and steadily. My natural pace is not above $1^{1}/_{2}$ miles an hour. If I try to double the pace, I tire quickly ; and if my legs are cold they soon become very tired. But, with all my care, I often fall. My reaction is quick and I am expert in escaping injury. This necessitates unremitting care. The chief causes of falling are inability to lift my feet high enough, which makes me trip over carpets, rugs, steps, stones, and similar obstacles ; a sudden turn with loss of balance and failure of my slow-reacting muscles to save me ; attempts to support myself when unsteady by grasping unsuitable objects (a hot pipe, a screen, a mobile table) ; and a trick of catching my right toe behind my left heel when walking. A light blow on the knee will stun the leg and cause me to fall at once, and it is highly dangerous to catch my stick in a hole (for instance, in a grating). Getting up after falling is a highly skilled acquired art. During my first year I could not take enough exercise to make me really tired, but I had for years a peculiar localised form of fatigue. This extended from my feet to 3 inches above the knees, equally in both legs, and was so severe that my legs felt only one desire, never to move again. The feeling was periodic, usually arising after slight exertion, and was worse in the morning. I could use my legs as I wished, by voluntary effort, in spite of it. It slowly diminished and is now occasional and seldom severe.

My own psychological reactions interested me. I had heard nervous patients describe a feeling like an electric shock run through them from head to foot—now I was to experience it myself. If I had a sudden fright, the electric shock passed from my waist to my feet. At an early stage in my illness I could trace the course of my large intestine from the cæcum to the sigmoid flexure, as wind passed along it. As I sat in a chair with my legs crossed, my legs were more prone to jerk if I was annoyed. I could walk better if I was happy than if I had been upset. All these effects steadily diminished and passed away.

I returned to work after $10^{1}/_{2}$ months. During all these 19 years I have periodically endured strains that would tax an average man—long operation days and heavy lists, driving a car long distances in a single day, playing two rounds of golf, and so on.

At every stage and in every way helping

MEDICAL LIBRARIES IN HOSPIT

BY A COMMITTEE OF THE MEDICAL SECTION
LIBRARY ASSOCIATION

THE reorganisation and re-grouping of hosp
taking place as a result of the National Heal
Act opens the way to a better-organised libra
Hospital authorities are being encouraged t
for all kinds of readers—doctors, nurses,
auxiliaries, and patients—and it is already app
they are faced with many problems. The nee
and guidance is urgent.

Medical librarianship is a highly specialise
and the present great expansion of library
likely to lead to a serious shortage of trained
This shortage should only be temporary. Th
Association has recently instituted a special
tion in medical librarianship, and, as opport
acquiring the necessary knowledge and experienc
the staff difficulty should not be so acute. For
the organisation and control of many libr
probably be entrusted to members of the ad
staffs or to part-time workers who are unlik
conversant with scientific literature and wi
methods.

The purpose of these hints is to help those
the immediate task of organising and running
library. No attention will be paid to the q
patients' libraries, since it is generally agreed
are best administered by the public libraries in
tion with the voluntary agencies that have g
good service in the past. Library provision for
medical auxiliaries presents special problems
engaging the attention of the professional org
more directly concerned, and will not the
considered here.

Regional hospital boards which are thi
establishing libraries for professional staff shoul
what library services there are already in t
Medical library provision throughout the count
uneven. London is better provided than any
in the world, and there are excellent medica
in the great provincial centres. Outside the la
the existing library services are incomplete
inaccessible. The specialist and the resear
usually have access to the large medical librari
the British Medical Association, the Royal S
Medicine, or the Medical Research Council, and
the National Central Library to the genera
resources of the country. University medic
libraries provide excellent services in each reg
use of these services should be encouraged and d

THE SMALL PROFESSIONAL LIBRARY

The need in individual hospitals is for a sma
for quick reference by the staff. The specia
interest of each hospital must be considered in

stock of the library and in maintaining a suit- : of current books: and the advice of a small e of the specialist staff should be regularly The care and maintenance of the library will as much attention as building up the initial Iost medical textbooks go out of date within rs and are superseded by new editions. Expendi- urrent books is therefore a recurring charge, and cogent reason for great care in book selection. the library within manageable limits and it as a live working unit, superannuated books discarded from time to time.

should be grouped according to subjects, so lers can readily consult them. All difficulties destroy interest in the library. Part-time ıssistance is essential, to keep proper library

An alphabetical card-index of the books must , to serve as a catalogue and as a record of s. Some books—dictionaries, directories, and —should be clearly marked: *For reference only; removed.* All other books should be available owing. A duplicate record of loans should be pt alphabetically in the names of both the books borrowers. Simple rules should be made covering od of loan allowed and showing to whom the of borrowing is extended. Several hospital and society libraries at present extend the privilege ctors in their district. The needs of auxiliary st also be considered.

JOURNALS

licals, which are an essential need of the scientific present special problems of selection, subscription, age. It will not be possible, and it is not neces- r hospitals to attempt to build up large stocks ical journals. Some 2000 medical periodicals lished each year and only the largest libraries rd to acquire and keep anything approaching e stocks. The publication of union-lists of als, the extension of schemes for coöperation and rary lending, and the ever-growing use of , 'Photostats,' and microfilms have done much e periodical literature more accessible. It is, r, very important to be able to refer at once to when any point of treatment or diagnosis is in and if the hospital library can apply part of its to the purchase of current journals this should e. An expenditure of £50–£100 a year would a valuable nucleus, but periodicals take up a eal of space and it costs money to have them

Just as he likes to choose his books the specialist nt to choose his journals, and he will probably be to some of the more important. Members of dical staff should be encouraged to present to ary the journals they no longer require for personal Precise records must be kept of the incoming cals, to ensure that volumes are complete. Care- ction should be made before binding for permanent . Volumes not required permanently in the hospital efully be transferred to a larger central library.

A GUIDING BOOK-LIST

lected list of books in English which are in steady d, giving alternative titles under each subject- g, has been compiled by this committee with vice of leading authorities in the various depart- of medicine. Encyclopædic works and highly lised monographs have been deliberately excluded his list, as it is assumed that they will be obtain- n the large central libraries. Copies of this book- d further advice on medical libraries may be had the honorary secretary, Medical Section of the y Association, Wellcome Historical Medical Library, uston Road, London, N.W.1.

My watch being wrong the other morning, I arrived at the station a few minutes early for my Victoria train. A London Bridge train came in first and I watched idly as the crowd threw themselves into the carriages. Suddenly I found myself counting heads. Of as big a sample as could be noted in the short time, about one passenger in three was out of breath. At this station the train times are a little erratic and it might have been that a few moments earlier arrival caused the sudden rush. But the Victoria one rolled in a minute late, and again there was an estimated third of the travellers visibly breathless—and the station approach climbs only the slightest of hills. My curiosity was roused sufficiently to repeat the observation next day, with almost the same result.

It is a fair guess that these speed merchants are sowing the seeds of a fine crop of coronary thrombosis, myocardial degeneration, and for that matter peptic ulcer. Most of the entrants in the morning race are regulars, and they probably start most days by bolting an inadequate breakfast. Then in the train, as soon as they get their breath back, or before, they light cigarettes or pipe. Since most of them are at least approaching middle age, they are asking for trouble.

"To what end," I asked myself, "is this desperate daily dash?" If punctuality at the office is so important, then surely punctuality at the station is as important, and therefore worth a couple of minutes' margin to catch the train with certitude and comfort. There is no sporting spirit about it, as their grim faces show. (Admittedly their expressions may only be evidence that they have scanned the daily paper; the only item which I do not find depressing is the crossword.) I pondered the problem—and was suddenly brought up short. My pulse was pounding; it was 95 per minute. Today I too had run that last bit. Being early yesterday had only been a fluke due, as noted above, to my watch being fast. The day before I had missed my second cup of tea, and the day before that I had almost lost the train. The finger I had been pointing at my fellows turned inexorably rks

SIR,—I hesitate to criticise so distinguished a colleague as Dr. Pardoy (Aug. 27, p. 398) but, putting personal feelings aside, I must let him have it straight, ex humero summo.

Before launching my main grouse, however, I would mention his inconsistency. He admits, apparently, that the disease was first reported by Thomas Pearce (himself, surely, a lover of "fair" play), professor of veterinary surgery at Widdecombe University, yet he refers to it as *his* disease. One has no wish to argue here as to who owns the copyright. This can, and unless Dr. P. is prepared to climb down, will, be done at the proper time and in the proper place.

No-one could find fault with his article on literary grounds: it is admirably lucid, very informative, written in simple, almost basic, English, and an exhibition of the results of many years of clear thinking and deep learning. The qualities displayed are the more dangerous, however, because from a scientific point of view the doctor's effusion is sheer balderdash. As everyone should know, Pearce's "3 cases" was a description of three phases in the same disease of one subject—namely, a mare. This unfortunate beast (suffering from some form of hereditary cyanosis) was in bad shape when handed over to me and my six colleagues and could by no stretch of imagination be described as a young adult. The ætiology of the disease in this, the only known example of it, was diagnosed during life as traumatic lordosis. Permission for P.M. was refused, but later interment (which almost spontaneously occurred) was carried out and confirmed the presence of ossa crepantia or "mobile skeleton."

Finally, please note that my paper of this year should be cited under the authorship not of Cobley et al. but of Cobbleigh et omn., and that my name is spelled:

THOMAS COBBLEIGH, M.WID.C.V.S.

linical association between the two.

e have had it brought to our very door. What
do about it ? The ideal is that everyone who
tonsils should use his own clinical judgment
st from all operations in any year in which
litis is prevalent until it is no longer so, even if
ns putting off all tonsillectomies from the early
until the end of February. It is not a question
te scientific proof ; but one of probability. But
one of death and mutilation. There is no
everyone to become convinced by personal
e.

rgument that tonsillectomy will not allow of
ll not hold water. My predecessor at Guy's,
. Steward, used to shut down all operations at
nts from October to March—a practice in which
d him and extended to all such operations about
ago, since when I did no operations on tonsils
he winter months. No-one came to any harm
And those who claim that a tonsil operation
done at once have long been confuted by the
lists which they have allowed to pile up all over
try. If they really believed that these operations
gent they would have clamoured years ago for
ssary accommodation.

e administrators help us ? Not by ordering. In
e reports in the press it seemed to be suggested
e excellent memorandum circulated by the
of Health last year was an *order* to desist. This,
ot, was faulty journalism : but it continued by
a pathologist on the postponement of the
on. If he was accurately reported this pathologist
o have gone beyond his subject. There is no
gical evidence whatever that tonsillectomy leads
ion of the body by way of the wound produced.
dence is clinical entirely ; and it is for us clinicians
le. We are less likely to persuade those who do
ognise the principle of the dominating lesion if
ople start to dictate. It is, however, the business
linicians. For every clinician today sometimes
across a case in which tonsillectomy may need
ration.

e is a way in which the administrators may use
fluence. Under no circumstances must they be
to put pressure on clinicians to perform operations
their better judgment. This must be opposed
er it arises. But they may be entitled to call a
here the opinion of the majority of the profession
st operations being done, as I think must be the
re ; and they can do it by withholding beds.
here a loophole should be left for the clinician
e exceptional case. And that ought to be met
insistence on a second opinion, not from another
or on tonsils but from a physician of his own
g. Some such administration as this might well
up not only to stop tonsillectomy in times when
poliomyelitis is rife but also during the whole of the winter all over the country.

Finally there are the parents. They are in the end the persons responsible for the operation being done. That very wise little old man, Lord Snell, deplored the diminution of parental responsibility as being one of the danger signals of today. These cases bear out his grave warning.

At sea. T. B. LAYTON.

THE DOCTOR'S PROFESSION

SIR,—May I express my admiration for this series of essays ? In my opinion they state very clearly the views of the minority who occupy the Christian position. Although they are unlikely either to edify or to win the approval of readers who divorce religion or the fear of God from living, they nevertheless deserve a place in THE LANCET, which claims to be a journal of medicine. Medicine untinctured by either politics or religion is a specialty which deserves a journal of its own.

Hill End Hospital, St. Albans. F. C. STALLYBRASS.

SIR,—Modern medicine owes much to Christian thinking and more to the Christian men and women who have been, and are, leaders in the profession. It was therefore surprising to see that two correspondents were protesting about the series of articles under the above title. In this generation of advancing materialism, with its many ugly forebodings, it is surely high time that we were considering again our work as doctors in the light of our historic national faith. This is reason enough to welcome the articles. We have no business to allow others to do our thinking for us.

Dr. Simmons (Aug. 20) appears to me to misrepresent the writer of the second article, who is singularly careful not to overstate his case.

1. The Christian doctor does not enter the world with a "hopeless attitude." The reverse is the truth. He is aware of man's corruption but is far more aware of God's power and plan to overcome that corruption.

2. If a doctor is concerned *merely* to relieve pain "his attitude is sentimental and, because it is sentimental, dangerous." No-one would suggest that it is a Christian's duty to withhold relief for physical pain and suffering, but, like the Master whom he feebly follows, he does desire first and foremost to preserve the divine gift of life.

3. I do not agree with all the article says about suffering but the writer does not fail to condemn those who refuse to use "all reasonable means" for its alleviation. The mystery of suffering is a very deep one ; it cannot be fully explained in terms of pain and disease on a physical level. Yet the Christian believes that he can see a little further into its meaning than the materialist.

4. The answer to Dr. Simmons's question is—Yes, we are an unhealthy society if we pay too much attention to the needs of the body and in so doing neglect the soul of man and the demands of God upon him.

Iver, Bucks. C. G. SCORER.

SIR,—I have read with great pleasure the admirable and timely essays in this series. As it is wellnigh impossible for those uninstructed in Christian ethic to appreciate them, I should like to suggest a few thoughts to your two correspondents who registered some classic arguments in disapproval.

Mr. Whittingdale (Aug. 20) prefers you to serve your readers with medicine "untinctured by politics or religion." It is not impossible to dissociate medicine from politics because political principles rarely interfere with the theory and practice of medicine. On the other hand, religious principles (particularly in relation to questions arising from sterilisation, abortion, birth prevention, and euthanasia) are challenged at every turn. Defiance of these principles prompted the Nazis to liquidate their disabled and perpetrate unmentionable atrocities for the sake of their own monstrous eugenics. Hence it is a good thing for your journal to bring to the careful consideration of its thoughtful readers the very necessary interconnexion between these two great branches of knowledge.

Dr. Simmons objects that there is a hopelessness about the attitude or belief which claims that man is cut off from God in toto and is therefore corrupted by disease and mortality. Man is not entirely cut off from God. If this were so, the situation would indeed be black. The Christian believes death and disease to be the logical outcome of man's original rebellion against God. Christ effected a reconciliation. But the consequences of a crime may continue long after the criminal has been forgiven. It would take a long essay to present the closely reasoned arguments for this belief in the fall of man and its dread consequences. Suffice it to say, man certainly *looks* fallen. Even now within his own nature there exists a conflict between duty and desire which is the result of his old sad rebellion. This is the common experience of us all and a cause, I believe, of many neuroses.

Dr. Simmons asks whether he must allow "pain and suffering to persist to the end that life may be prolonged." No, indeed. In the first place pain is not allowed in order that life may be preserved. Life is preserved and consequently pain is endured. The Christian doctor is bound in charity to alleviate severe suffering as much as he is able. He can never appropriate to himself the right to extinguish his patient's life.

Your correspondent suggests that the Christian doctor "must not go to all lengths to alleviate suffering by the method of modern medicine." If by this he means that the Christian doctor is not entitled to employ a lethal dose of sedative to vanquish pain, he is right. He blesses the nerve block in cases of inoperable cancer. So do we all.

Finally Dr. Simmons asks whether the writer of the essays regards the National Health Service, providing indiscriminate care for all, rich and poor alike, as the outward expression of an unhealthy society. This is a very sad interpretation of the writer's meaning. There appears to be no contradiction in the existence of the National Health Service and the principle "Love thy neighbour as thyself." There is certainly nothing unhealthy about the principle of mutual love and its application to the present health scheme—or any other scheme that attempts to serve society and promote its welfare.

In conclusion, may I emphasise the importance of constant vigilance lest the great religious principles which govern our lives should be allowed to fade out of the field of medical science? If they are ignored, we shall have an undisciplined science open to mortal abuse.

Lancaster. F. S. RICKARDS.

SIR,—As a LANCET subscriber I confess to sharing the irritation felt by Mr. Whittingdale (Aug. 20) on account of your articles under this heading (though for a different reason). I would like emphatically to protest against his view that Christian values have nothing to do with medicine, for this is what I take him to mean.

I believe that sickness of men's souls brings them to the doctor as *often* as—if not more often than—sickness of their bodies, when they, having no idea of the fundamental cause of their symptoms, turn to the doctor rather than to the minister of religion; and that in these circumstances the patient is fortunate whose doctor is competent to diagnose soul-sic[illegible] d co[illegible] eous enough to be frank about it.

I should like to ask Mr. Whittingdale what would give to a patient who yearns to give or tobacco, yet has no will-power to do so; out that Dr. J. A. Hadfield, in his *Psychology* (p. 96), states that religious conversions have (instantaneously) the same effects as succe therapy (which may well be prolonged). It pointed me to Begbie's book *Broken Ea* actual examples of the *changes for* conversion can work in men and women.

The doctor who is not a Christian—that is, constantly careful about beams in his own e competent to perceive spiritual causes of s others. I think therefore that space in a journal might properly be devoted to showing as can be shown, that Christian belief is not less than the dispassionate investigation, m of the thought, words, and deeds of daily teaching which claims to be Truth. The would follow might well be immense.

Winfrith, Dorset. P. R. B

SIR,—I wish to thank you for the excellent essays in this series. As a Christian trying, ferently, to apply my religion to daily work a practitioner, I find it invaluable to have the so clearly discussed.

I disagree with Mr. Whittingdale (Aug assumes that these articles are "outmoded" you of "senile decay." I, for one, continue t to your journal *because* you continue to publ with a wider viewpoint such as these and the Disabilities series.

Farnborough, Hants. J. P

SIR,—It is unfortunate that your co Mr. Whittingdale (Aug. 20), should have sin *Church Times* as an example of the kind of which specialises in "outmoded evangelical Christian ethics." Those who happen to of that worthy journal will be surprised and hear the word "evangelical" used in this Incidentally, the journal in question has distinguished for its interest in ethics, otherwise.

The series of articles on the Doctor's Profes it should be understood, is the work, not or ecclesiastics, but of members of our prof strike many as neither "evangelical" nor "o but plain common sense. My impression American parlance, "there ain't no flies" on have written them. This is not the work obscurantists. It is because so many have do look, for that anomaly, a "Medicine unti either politics or religion" that some at least impelled to set forth this holistic conception practice.

I admire their courage, and hope that they reveal their identity.

Leamington Spa. F. S.

SIR,—Congratulations on the second article heading. It was inevitable that a condensed of Christian ethic and its relation t the medicine should be misunderstood by hose w already know its main tenets. Wit rega expression "fallen world" that Dr. Simmons much, let him realise that the facts ar that suffer more or less during their lives, an that die. The Christian doctrine of "the fall" is a tion of why this happens.

The questions of the purpose of suffer of man's existence, the presence or absence of death—all these have haunted men thr On the answer a man gives to these quest es my behaviour here have any effect on my death? depends a man's practice of life and tails of a man's practice of medicine. That Whittingdale's implicit insistence that medifluenced by religion, or unconnected with it, ous.

no was God) did not suggest we employ go-slow medicine. It is merely that the first aim of to safeguard the gift of life: its secondary elieve suffering. Consider surgical operations. increase suffering temporarily for the purpose ife.

cn Tyne. P. S. TWEEDY.

a professing Christian and as a doctor long of the significance of social, personal, spiritual, is states to medical ætiology and therapeutics, elf in general agreement with Dr. Simmons ism of one important paragraph in the second his series. I refer to the paragraph headed Doctrine" on p. 293 (Aug. 13). The two views nature (and hence of the origin and nature uffering, and sickness) there described are, ssert, only two of several alternative Christian my mind, the ideas implicit in the doctrines depravity" and of the existence of an stinction between the natural and the superre not only intellectually incoherent but ub-Christian.

H. E. COLLIER.

ome of your correspondents seem to find the Christian ethics difficult to swallow and would see them omitted from your columns. In my LANCET is to be congratulated for putting readers an Anglican statement of Christian ich, though not acceptable by all, should in r concepts be a wholesome guide to doctors the name and a positive antidote to scepticism, ism, and nihilism. I believe that those "prointellectuals who, in these feverish and strongly ve times, have broken with, or have never opportunity or the patience to embrace, the f our traditional beliefs and practices, including s, show unmistakable evidence of immaturity of it, mind, personality, or what you will.

S.W.17. A. WYNN WILLIAMS.

My inclination to congratulate you on the earlier this series was strengthened by reading the om Dr. Simmons and Mr. Whittingdale, who seem derstand the authors' argument, which was least designed to set the "problem of pain" oper perspective. The subject has been well a book of that title by C. S. Lewis; and more Martin d'Arcy in *The Pain of this World and the e of God*. It is a problem to which the Christian hough to many unacceptable, is relatively simple. hristian answer, however, may well seem nonthe man who does not accept fundamental beliefs; to such a one an uncomfortable ethic is "outmoded," as though absolute truth troyed by the lie of the moment, or as though epended for its existence on acceptance in a tic age by a majority. The fact is that God made d made them for definite ends. This is the basis atural moral law. It is a fact which cannot be by a sneer, nor altered by its unacceptability or to many. It is a fact which should not be to the relative obscurity of a church paper read few, since it is a vital part of the ethical ind of us all.

HILARY.

TUBERCULOSIS IN CHILDHOOD

SIR,—In his article of Aug. 13 Dr. Miller cites unequivocal evidence that tuberculosis is of importance to the pædiatrician. However, this hardly justifies his assertion, as a pædiatrician, "that the tuberculosis service as a whole gives insufficient attention to childhood infection and the toll which tuberculosis exacts from the children of this country." Pointing out that the mortality from tuberculosis under the age of 15 years accounts for only 10% of all tuberculosis mortality, he suggests that this "may explain the view current in the tuberculosis service that the problem presented by childhood tuberculosis is relatively small."

Tuberculosis physicians have greater justification than this for not paying any greater attention than they do (which is not negligible) to this disease in childhood. Every pædiatrician will presumably agree that the good health and survival of the parents are an important factor in the healthy upbringing of children. More widely, the health of a community is related to its economic stability, and both depend inherently on the health and working capacity of young adults. Stocks[1] has shown that in 1945 the number of expected working years lost because of deaths from tuberculosis was 565,300, in comparison with 354,600 for cancer, and 268,200 for fatal accidents. Tuberculosis damages the productive capacity of this country more than any other single disease, almost equalling in its ravages the loss of expected working life caused by cancer and fatal accidents together. The tuberculosis physician, realising this, and having a wider perspective on the disease generally than the pædiatrician, is justifiably apt to direct more attention toward young adulthood—the bread-winners of the nation and the family.

During the last fifty years in this country, by far the steepest decline in mortality has been among children. The mortality-rates quoted (from Hart and Wright[2]) in table I show that the decline among young adults, especially females, affords least ground for satisfaction.

TABLE I—MORTALITY IN ENGLAND AND WALES FROM RESPIRATORY TUBERCULOSIS PER 100,000 LIVING, BY AGE AND SEX DURING 1891–1936

Years	Age (years) and sex													
	0–4		5–14		15–24		25–34		35–44		45–54		55–64	
	M	F	M	F	M	F	M	F	M	F	M	F	M	F
1891–1900	44	39	20	37	141	144	237	192	310	122	314	164	262	124
1901–10 ..	35	30	15	29	112	111	197	148	245	155	275	131	238	105
1934 ..	8	6	5	8	72	99	94	91	107	60	139	47	115	36
1935 ..	6	7	4	8	64	93	90	85	106	57	126	42	117	37
1936 ..	7	7	3	7	59	88	84	78	98	53	128	41	120	36

Dr. Miller observes that in 1945 the tuberculosis mortality-rate in the age-group 0–15 years was 25·2 per 100,000 living. However, for the same year the corresponding mortality-rate (civilian plus non-civilian deaths related to the estimated total mid-year population) among young adults was as follows:

Age (years)	*Mortality-rate per 100,000* Males	*Mortality-rate per 100,000* Females
20–24	67 ..	96
25–29	70 ..	83

In other words, although tuberculosis killed 25 out of every 100,000 children, it was more than three times as deadly among the "young parents" of the population.

---

1. Stocks, P. *Tubercle*, 1949, 30, 50.
2. Hart, P. d'A., Wright, G. P. Tuberculosis and Social Conditions in England. London, 1939.

To assess the devastation caused by tuberculosis more completely, one must compare the number of deaths it causes with the number of deaths due to other diseases in various age-groups. Miller has done this for children, and table II (derived from the *Registrar-General's Statistical Review for 1946*) shows the number of deaths from certain common causes in selected adult sex-age groups (civilian plus non-civilian excluding operations of war). These are arbitrarily selected to represent what might be called "young parenthood," "middle age," and "retiring age"—i.e., 20–25, 40–45, 60–65. The six causes listed in table II account for 75% of the deaths in the age-groups that have been selected. Obviously, by causing one-third of the male deaths and half the female deaths in the 20–24 age-group, tuberculosis is the disease most damaging to the productive capacity of the community; and thus the attention of the tuberculosis physician is rightly focused on this age-group, who are also the patients most likely to benefit from modern treatment.

TABLE II—DEATHS IN 1946 AMONG SELECTED AGE-GROUPS FROM SIX COMMON CAUSES, EXCLUDING DEATHS DUE TO OPERATIONS OF WAR. THE PERCENTAGE OF DEATHS WITHIN THE SEX-AGE GROUP DUE TO EACH CAUSE IS SHOWN *IN PARENTHESES*

Cause of death	Age (years) and sex					
	20–24		40–44		60–64	
	M	F	M	F	M	F
Tuberculosis ..	905 *(34%)*	1542 *(55%)*	1256 *(18%)*	618 *(12%)*	1111 *(4%)*	336 *(2%)*

What is the relation between primary infection and the development of significant illness from tubercle bacilli? The prognosis of primary infections generally, at all ages except infancy, is apparently good—most people undergo Mantoux conversion uneventfully. This is in sharp contrast with phthisis, which kills more than half its victims within three years.[3] Wallgren[4] believes that the symptoms of primary infection occur six weeks or so after actual infection, and there follows a three-month period during which the malignant generalised forms of the disease may supervene. Then comes the pleurisy period, from about three months to seven months after the manifestation of primary infection. After this phase there remains the risk of skeletal tuberculosis—a *hazard which continues* roughly three years after infection until the primary complex has healed. In those persons with primary infection in adolescence this stage corresponds to the period of post-primary pulmonary tuberculosis. Wallgren finds that most cases of phthisis occur during the first three years after the manifestation of the primary infection, but that cases *also develop later* with rapidly decreasing frequency.

This view of the relation between primary tuberculosis and phthisis is very important, and other evidence that phthisis follows in the wake of the primary infection is to be found in the ever-growing literatu There seems to be less and less need "reinfection," and "superinfection" in t of phthisis.

Gaisford[5] has advocated tuberculin-te ren as the prime measure for solving th primary tuberculosis in childhood. Ext culin testing is certainly most necessary, problem is post-primary disease in adults

Tuberculosis physicians will readily ag Miller that the only method of controllin in childhood is to prevent infection—hen occupation with controlling the infective a theless, their preoccupation with adults do exclude their concern with children, alth slightly different aspect. General practi refer children with *the vague symptoms* d infection to the children's department rat tuberculosis physician. However, the tube is constantly searching for uninfected child contacts of known cases, and so he discover number of recent primary infections w probably keep under surveillance for two o or perhaps longer, after puberty. At pre approximately 130 such children under s this clinic. Twice since the advent of *the discovery of the primary infection* b helped a general practitioner in this tow tuberculous meningitis early and so bring result from chemotherapy.

The tuberculosis officer is concerned wi negative children from the preventive as tunately, lack of B.C.G. hampers our efficie with this group. In Reading there are a contact children under surveillance, but mere handful of these come from the sputum-positive cases; such children are us before they are discovered. These children a tested at regular intervals, and besides "timing" of primary infection such tests a ment of the sputum-negative patient in t

A third group of children are referred t this town from the infant-welfare centre, w of children under 5 years are undergoing culin tests. All the tuberculin-positive passed on to the tuberculosis service; *need be done about the primary* infec endeavour to find the infective source.

I do not think that pædiatricians and physicians differ in their concern for ch extent that Dr. Miller fears. The pædiatri with sick children, and to him tuberculosis large in differential diagnosis. The tuber seeks, by epidemiological methods, to preven in children. We have not yet attained th when we can reproach ourselves for the oc primary infection; the tubercle bacillus fin before middle age.

ases on chemotherapy, with the infected hand
lised—factors which they themselves admit
ably reduced the incidence of serious complica-
Exploration of infected hands for sloughs, unless
iously performed, must inevitably break down
ive barriers and tend to spread infection. Anyone
practised surgery before the days of chemo-
y remembers the tragic case (sometimes in a
ue) where injudicious incision of a finger resulted
strous lymphangitis or even septicæmia. Attempt-
hunt for sloughs in a finger which is really the
of lymphangitis. and not a pulp infection—a distinction not always easily made, as Kanavel[2] pointed out—may have unpleasant effects even today.

Following a paper by Mr. T. I. Wilson[3] read at a recent meeting of the Medico-Chirurgical Society of Edinburgh, Mr. W. Quarry Wood presented a series of 405 cases of infected hand treated conservatively by chemotherapy without any operative treatment except for pricking a residual purulent blister:- there was no case of necrosis of bone or any other complication. and all the cases made complete recoveries without any kind of disability. These cases were in nurses, and the majority were treated from the earliest stages; but. as Dr. Verney pointed out. there were a large number of advanced and gross infections of the hand among them. which had arisen from concealment of the symptoms.

With such satisfactory results from conservative treatment. I am not convinced that the drastic procedures advocated by Mr. Arden and his fellow workers are to be preferred; I have no doubt at all which method I should choose if I were the patient.

Edinburgh. JAMES A. ROSS.

HEARING-AIDS

SIR,—I read with interest Mr. Read's letter in your issue of Aug. 13. Discussing the 'Medresco' aid. Mr. Read claims that "no training whatever in the use of aids has been given." If this were true the 4000 aids issued in this clinic during the past year could have been handed out in less than a month. The time represented by the remaining eleven months was taken up mainly in trying to provide the training which Mr. Read says is not taking place.

Royal National Throat, Nose, and Ear Hospital, London. EDITH WHETNALL Director of Deafness Aid Clinic.

SPLENECTOMY AND THE HÆMATOLOGIST

SIR,—Your leading article of Aug. 6 calls attention to so many important points that it is the more lamentable that there is no reference to the value of spleen puncture.

In the past. with no easy method of obtaining bone-marrow during life. we did the best we could by drawing inferences as to the state of the hæmopoietic organs from the character of the blood-picture; but now, in any obscure anæmia. marrow puncture is done. and it is indisputable that diagnosis has become more accurate. You appear to suggest that, in the investigation of splenic disorders, blood and marrow examination are all the diagnostic aids at our disposal: this is. of course. not so, because spleen puncture is almost as easy and as safe as marrow puncture. Admittedly, only in certain cases is it essential for diagnosis; but in these it is often the only method of reaching a definite decision. The method is by no means new, having been the subject of a monograph as long ago as 1936[4]; while much more recently it has been discussed by Moeschlin.[5] Indeed, I would say that spleen puncture should now be regarded as a routine hæmatological procedure where there is no contra-indication.

In the same article, you appear to agree with me[6] in deploring the scarcity of hæmatological physicians; and yet you do not criticise the modification of the M.R.C.P. examination, which will no longer demand a knowledge of microscopy (p. 254). If those whose "knowledge of general medicine justifies further training as a consultant" (p. 252) are not to demonstrate the possession of some knowledge of hæmatology, it is difficult to imagine where the hæmatological physicians of a new generation are to come from. Of course, it may be that they will have to train themselves, as we of the present generation have had to do. That would, in my opinion, be excellent, but I have the gravest doubts whether the modern "planner" would be prepared to leave that amount of freedom in his circumscribed world.

PARA-AMINOSALICYLIC ACID IN TUBERCULOSIS

SIR,—In the following case of tuberculous ulceration of the tongue and epiglottis, a dramatic result was obtained by administration of *p*-aminosalicylic acid.

A man of 42 was admitted under my care on Dec. 18, 1947, with bilateral tuberculous disease of the lungs. There was a small tuberculous ulcer at the tip and a larger ulcer on the right margin of the tongue; the epiglottis was free of disease. The sputum contained tubercle bacilli. The patient was submitted to a general sanatorium régime. Locally the tongue was treated with 10% 'Promanide' spray, and the marginal ulcer was cauterised by Mr. W. H. Bradbeer. At the end of March, 1948, he was discharged to attend to urgent business. His weight, which had been 9 st. 12 lb. on admission, was now 9 st. 13 lb.

He was readmitted on Oct. 14, weighing 9 st. 2 lb. His general condition had deteriorated. The ulcer at the tip of the tongue had healed but the marginal ulcer was larger and was intensely painful; the epiglottis was now ulcerated and swallowing was extremely difficult.

On Nov. 5 he began to take by mouth the sodium salt of *p*-aminosalicylic acid in a mixture containing to each 3 g. of the drug 1 drachm of syr. aurantii and water to $^1/_2$ oz. The patient received five doses of 3 g. between 6 A.M. and 6 P.M., with a single dose of 6 g. at 9 P.M. Locally, the ulcers were sprayed twice daily with a 10% solution of the drug.

Within three days the pain subsided and appetite returned. The ulcers steadily decreased in size. By the beginning of April, 1949, the tongue had healed firmly and the ulcer of the epiglottis appeared to be quiescent. Clinically and radiologically the pulmonary lesions were unchanged. The sputum, which had been negative for tubercle bacilli on Dec. 13, 1948, was positive on Feb. 14 and again negative on April 27. The patient was discharged on May 5, weighing 9 st. 13 lb.

In my experience *p*-aminosalicylic acid, prescribed in the way described here, gives rise to very few troublesome symptoms; nausea and diarrhœa have always been transient and have subsided promptly when the medicine was discontinued for 48 hours. In my opinion the preparation may be safely administered in the home, and I suggest that early cases awaiting admission to a sanatorium should receive a course of it while having bed rest at home.

Torquay. GEORGE T. ALLERTON.

PREVENTION OF BURNS AND SCALDS

SIR,—In your issue of July 30 Dr. and Mrs. Colebrook discussed prevention of burns and scalds in the home. They did not mention one very dangerous practice—i.e., the use of inflammable materials for "home work" on partly finished factory articles such as rubber and crêpe soled footwear. One young woman in my experience lost her life from the accidental "spillage" of a solution supplied to her husband for "home work," and now a greater disaster has occurred in Bristol from the spilling of a solution for fixing heels to shoes.[1]

It should be possible—and it certainly seems desirable —to forbid the use of rubber solution in "home work." Unfortunately it is always a temptation for those on a low rate of pay to take up easy "home work" such as the finishing of rubber shoes, to help out their earnings. It is not realised how high a risk attaches to the process. It may be all right in a properly designed and equipped factory where all the workers are properly trained, but should be prohibited in the home.

Surrey. W. EDWARDS.

ANXIETY NEUROSIS

have read with interest the two illustrative
1 anxiety neurosis appearing in your issues of
1d 20. I am convinced from my own experience
tions of various doctors to this type of disorder
of the greatest obstacles to the treatment and
urotic illness lies in the difficulty many doctors
accepting the validity or the reality of these
ces, and all the misery they produce. They
deny the existence of anxiety of an intensity
on beyond that encompassed by their own
e, and they fail to understand that feelings
dered may be strong enough to overcome a
ocial responsibility comparable with their own.
en forced, by overt changes in the behaviour of
nt, to admit that something is wrong, most of
ard it as a sort of moral lapse to be covered up,
d away by reassurance or by a fatherly homily
ling up one's socks." Owing to his excessive
patient is only too ready to reinforce a moralistic
, and he makes further attempts at repression,
nay be superficially successful but which really
conflicts and symptoms. Some will then
irrational or antisocial behaviour, which excites
affled doctor a desire to chastise. This may well
tor in the present disproportionate popularity of
onvulsive therapy and such mutilating operations
otomy—not to mention the general corrective
towards patients in mental hospitals.

ems that these reactions in the doctor result from
wareness or misunderstanding of the nature of the
state in a neurotic or psychoneurotic illness;
1 his fear of feeling helpless if he once admits
1e patient does have such difficulties, and that
an, in fact, interfere greatly with his personal
ess and to a lesser extent with his social conduct
efulness. Patients are testifying to facts, and
despread incidence of emotional difficulties in the
nity at large bears them out. To deny these
unscientific. Doctors must accept them if they
have a better understanding of the causation,
ent, and prevention of mental illness.

1 writers of the "Disabilities" articles made it
lear that an anxiety neurosis is an illness affecting
1otions, and not primarily interfering with either
elligence or the social responsibility of the patient.
90% of the disturbance consists in subjective
nal phenomena of an extremely unpleasant nature,
are not manifest to the casual observer, or are
nt only in the guise of "peculiarities" such as
ability, bad temper, indecisiveness, or obsessional
Thus if a major breakdown is to be avoided, it is
al that the doctor should listen to, believe, and
eriously what the patient says.

n attempt to explain to some of my colleagues the
tive clinical picture of my own anxiety state, I wrote down the following observations, which may be worth repeating in support of the evidence in the articles. The subjective symptomatology could be defined as the changes in the "general view of life," which rose and fell, with variable frequency and velocity, but with invariable continuity and order, within the following span: (1) ecstasy; (2) enthusiasm; (3) pleasure; (4) tolerability; (5) intermittent uneasiness; (6) frank low-grade anxiety; (7) spasms of severe anxiety with fear or guilt; (8) established anxiety with periods of panic; (9) "intolerable" or "hopeless" anguish; (10) fatalistic unreality with compulsions. Each of these stages had its accompanying physical, intellectual, and emotional aspects, which I will not describe here; but the well-defined directional pattern indicated the organisation underlying a genuine pathological entity, and this gave the lie to the "black magic" explanation which I, and others of my acquaintance, had been wont to accept regarding neurotic symptoms.

There was nothing, at least in the first seven or eight stages, fundamentally different from the experiences of many people under various external stresses and strains. The unusual features were the duration and severity of the disturbance (stages 7, 8, and 9 being predominant for hours or days at a time, and hardly twenty-four hours' consecutive "tolerability" being experienced over a period of many months); and the absence of any rational explanation, in the material circumstances, for the panic reactions. Psycho-analysis provided the rational explanation by linking up the buried conflicts of the past with the panics of the present; and when emotional as well as intellectual fusion of these is attained, the panics do not have to be conquered—they dissolve.

A FELLOW-SUFFERER.

CHRONIC AND UNEXPLAINED ŒDEMA

SIR,—With reference to the article by Dr. Whitfield and Professor Arnott in your issue of Aug. 6, I should like to suggest an additional method of treatment for chronic œdema, which has proved, in my experience, more satisfactory than any of those mentioned.

It consists in the use of radiant heat applied to the legs for about half an hour, followed by careful massage and some exercises against resistance. This should be followed by bandaging the patient's legs and allowing him to walk about freely.

London, W.1. P. S. FLEISCHMANN.

MIGRAINE

SIR,—Dr. Hay's letter of Aug. 20 draws attention to the fact that—contrary to the opinion of many—migraine is not entirely resistant to therapy.

Vasoconstrictors and anti-histamine drugs when given early enough will prevent the onset of attacks in some cases; but they do nothing to alter the pathological condition which is the cause of the disease. For the patient it is the perpetual fear of headache that is so depressing, since no future arrangement is ever safe from interference.

Migrainous attacks can be divided broadly into two classes: (1) those with an underlying endocrine dysfunction (typified by the "menstrual migraine" of women, but present in men too); and (2) those associated with histamine sensitivity, which by some unknown mechanism appears to result in hemicranial arterial dilatation.

It is true that some cases resist all forms of therapy. But the success of treatment with anterior-pituitary-like hormones in cases of endocrine migraine,[1] or with histamine or neostigmine desensitisation in those giving a positive intradermal test,[2] is encouraging often enough to warrant universal trial in place of the routine "aspirin and bed." This type of therapy is directed to eradicating the attacks, or at least reducing their number and severity, rather than to aborting a headache when it arrives.

A LIGHTWEIGHT RESPIRATOR

SIR,—The account of the Monaghan respirator given in your issue of Aug. 13 (p. 308) did not describe its mechanism. It acts on the principle of alternating negative and normal pressures within the dome of the cuirass, through which movement of the abdominal wall and anterior part of the chest effects descent and relaxation of the diaphragm and some expansion of the chest. It is therefore merely a limited application of the principle which operates in the Drinker respirator. There are six sizes of cuirass. I recently saw and tried the machine in the U.S.A. and feel that it has a value in cases which require some assistance but not complete dependence upon a respirator.

Western Hospital, W. HOWLETT KELLEHER
London, S.W.6. Physician-Superintendent.

PROS AND CONS

SIR,—Professor Alstead's statement, in discussing the membership examination last week, that "nobody willingly submits to the depravity of acting as an examiner save from a sense of duty or out of regard for the financial reward," must not be allowed to go unchallenged.

It has been my privilege and pleasure to examine for one of the specialist diplomas, and my term of office was not only enjoyable but also instructive. Meeting one's colleagues, and learning from them and the candidates, has been a stimulating experience which has done much to remove my sense of isolation as a provincial teacher. I hope examining boards, when appointing their examiners, will keep this aspect in mind and recognise the value of an examinership to younger provincial teachers.

EX-EXAMINER.

OSTRACISM OF THE TUBERCULOUS

SIR,—I am grateful to Dr. Foster-Carter (July 30) for his generous support of my plea for the tuberculous (July 16).

The evil is not confined to the British Isles. I have personal knowledge of a family of healthy people who were emigrating to the U.S.A. to join relations long resident in that country. No symptoms or signs of disease were present in any member of this household; but because an obsolete, calcified lesion was discovered in the wife's chest her visa was cancelled, the family's plans ruined, and a stigma placed upon them that they may never outlive.

A naval pensioner for tuberculosis was discharged from the Service with his disease quiescent, and obtained work as a clerk with a gas undertaking. Whilst so employed he unfortunately developed signs of reactivation and was admitted to a sanatorium, from which he was ultimately discharged with a selective artificial pneumothorax and with his disease quiescent. He was now fit to return to work; but a deputation of his fellow workers told the manager that if he came back they would leave, as they had no intention of taking tuberculosis back to their families. The manager, in spite of medical reassurances, timorously gave in and referred the matter to London. There the matter rests. The patient is left in agony of mind, fearful that without
cause and by the influence of ignorance, pre
uncharitableness his livelihood may be taken

Obituary

HIBBERT ALAN STEPHEN NEWTON

KT., M.S. MELB, F.R.C.S., F.R.A.C.S.

Sir Alan Newton, a former president of the Royal Australasian College of Surgeons, who died on Aug. 4, was one of the acknowledged leaders of surgery in Australia.

Hibbert Alan Stephen Newton was born in Melbourne in 1887, the son of Hibbert H. Newton, Clerk of Parliaments, Victoria, and he was educated at Haileybury College, Melbourne, and the University of Melbourne, where he graduated M.B. in 1909, obtaining first place in the final honours lists and the Beaney scholarship in surgery. After holding posts at the Melbourne Hospital as resident medical officer and as registrar he was appointed an honorary surgical clinical assistant in 1912. In the same year he obtained the M.S. of the University of Melbourne. Before his appointment the following year as surgeon to outpatients at the Melbourne hospital he spent several months in London working under Sir Victor Horsley at University College Hospital and at Queen Square.

[Barratts

During the 1914–18 war, with the rank of captain and later of major in the A.A.M.C., he served for a time in a casualty-clearing station in France, and in 1919 he was attached to the 3rd Australian auxiliary hospital at Dartford; it was while holding this appointment that he obtained the fellowship of the English college.

After his return to Australia he resumed his appointment as surgeon to outpatients at the Melbourne Hospital, and in 1927 he was appointed surgeon to inpatients and lecturer in clinical surgery.

Although he had one of the busiest surgical practices in Melbourne, Newton had many other interests. He was associated with the early formation of the Melbourne Permanent Postgraduate Committee, and he was one of the prime movers in the foundation of the Royal Australasian College of Surgeons. Its development owes much to his influence, and he held the offices of censor-in-chief, vice-president, and from 1942 to 1945 of president. He was also a member of the councils of Trinity College and the University of Melbourne, the board of the Walter and Eliza Hall Institute of Medical Research, the medical board of Victoria, and the council of the Victorian centre of the St. John Ambulance Association. He was an honorary fellow of the American College of Surgeons and a fellow of the British Association of Surgeons. In 1936 he was appointed knight bachelor.

During the late war, with characteristic vigour, he did not spare himself despite his failing health. From 1939 to 1945 he was a member of the Central Medical Coördination Committee and for three years he was deputy chairman. He was appointed consulting surgeon to Army Headquarters in Melbourne, and from 1940 to 1945 he held the highly important post of chairman of the Medical Equipment Control Committee. In 1942 he was as quick to realise the vital necessity of getting all the quinine possible out of Java, as he was later to appreciate the need to speed the manufacture of other essential drugs such as sulphaguanidine.

In his later years, Newton's health did not permit him to continue his practice, but in 1947 he was appointed Stewart lecturer in surgery at Melbourne, and here he carried on with determination but at last succumbed to an illness which had almost carried him off a year earlier.

An Australian correspondent adds: "A general surgeon of great merit, Newton was particularly interested in the surgery of the thyroid. He was devoted to teaching and in this he excelled. His students, who held him in great affection, flocked to his ward-rounds and lectures. A man of outstanding personality, he had a tall and imposing presence and a grand manner. He had a great influence on the development of surgery in Australia, particularly in Melbourne, and so long as there is a Royal Australasian College of Surgeons there is likely to be a special shrine for Newton."

In this country Newton had also many friends, and his British colleagues Sir Gordon Gordon-Taylor and Prof. C. Lambert Rogers write: The death of Alan Newton has robbed the southern hemisphere of its dominant surgical figure. From the first he seemed to have been created in the heroic mould: fortunate in his parentage and forbears and in his educational background, he was destined to take the leading place, assured and unquestioned, in whatever profession he chose. His particular vintage year of medical undergraduates at Melbourne University was brilliant, yet in this galaxy of able young men Alan Newton secured each session the premier place with ever-recurring, almost mathematical certainty.

A visit to England in his early postgraduate period brought him into close contact with such stimulating personalities as Victor Horsley and Arthur Hurst. The atmosphere of Horsley's experimental neurosurgical laboratory remained an unfading influence with him, and in the early years after the first world war he continued in Osborne's physiology department in Melbourne the work he had begun in University College, London. The catholicity of his surgical interests, however, may be gauged from his writings, and although his name is perhaps pre-eminently associated with thyroid surgery, his communications to the medical press—he was most loyal to the *Medical Journal of Australia*—embraced almost every aspect of surgical work. In the treatment of the mundane hernia his operation was based on the method first described by his fellow citizen and former teacher, Hamilton Russell: he could deal with a gastrojejunal ulcer with the consummate artistry of Moynihan or Bland-Sutton; his successful end-to-end suture of a pancreas ruptured by a playful pony's hoof rightly belongs to the annals of abdominal surgery; as a good anatomist, who had also been a lecturer on surgical anatomy in Melbourne University, he displayed a preference, where possible, for the incision along the outer border of the erector spinæ for the exposure of the kidney rather than the carnivorous Morris incision which bisects the unfortunate patient. His paper on gunshot wounds of the cranium, in the *British Journal of Surgery* in 1919, doubtless bore the impress of Harvey Cushing as well as Horsley, for he had made contact with the great American neurosurgeon in the Ypres salient in 1917. In all Alan did his gentle, precise, bloodless, yet rapid technique revealed him to be one of those natural surgeons whom the tissues obeyed.

Nature had endowed him with the gift of stature and he commanded notice in the crowd and in the councils and assemblies of men. None who have attained the dignity of the woolsack of the Royal Australasian College of Surgeons can have worn its presidential robe more correctly or fittingly or conducted meetings with more decorum; and yet we wonder whether he may not have achieved more in his efforts to promote the prestige and influence of the college which he had so much at heart during the many years when he was censor-in-chief and the power behind the surgical throne. He possessed all those qualities which make for leadership, but he was more than a leader, he was a statesman indeed.

It has sometimes been said that orators are not often successful statesmen, but Alan Newton's sagacious surgical statesmanship was beyond all cavil. His able chairmanship, his marvellous vision and rapid decision in connexion with the Medical Equipment Control Committee made him one *qui de re publica optime meritus est.* Those who have listened to his oratory will remember his addresses for all time, for the mastery of phrase, the wondrous imagery of words, the impeccable English, and the sentences that flowed with almost contemptuous ease, commanding attention and sweeping away opposition like a river in spate, placed him in a class to which Moynihan or Paget belong.

"He does not die who can bequeath
Some influence to the land he knows."

Sir Alan Newton married in 1919 Miss Mary Cicely Wicksteed of Headingly, Yorkshire, who survives him with a son and a daughter.

THOMAS CRISP ENGLISH

K.C.M.G., M.B. LOND., F.R.C.S.

Sir Crisp English, consulting surgeon to S Hospital, died at his Norfolk home on Aug age of 71. We owe the following memoirs colleagues:

* * *

When I first joined St. George's Hospital year student, Crisp English had just finished appointments and soon afterwards, in 1903, final F.R.C.S. examination while still under I entered the wards he had just been appointed surgeon at the early age of 26, and he soon mark as a forceful teacher and a brilliant, speedy, and accurate operator. He was, at that time, always willing to take risks and to embark on new and difficult procedures. As far as I am aware he was the first surgeon at St. George's to perform gastrectomies—in those days for malignant diseases only—and to remove the gasserian ganglion for trigeminal neuralgia. I was his house-surgeon when he was senior assistant surgeon and I owe much to him for the help and advice that he gave me then and later. He was always ready to help his juniors by advice, by actual assistance at operations, and more valuable still by the use of his beds for their cases.

During the 1914–18 war English, after a s of service in France, was transferred to Salo he served with distinction as consulting surg in France he did much to emphasise the advocated and applied by Owen Richards only rational treatment for abdominal wou early operation. After the war his priva became so large and burdensome that he himself in his hospital work with the and accurate performance of relatively mi procedures and tended more and more to a interferences likely to be fraught with difficult Though continuing to teach he left a considera of his routine work to his juniors. Outside hi English had few interests and apart from in his younger days he had no inclination towa recreations. He was, however, a past Goldsmiths Company and took a great in work of that body over a long period. Dur few years he had been in failing health and was accentuated by the death of his wife, was devoted, some three years ago.

My first meeting with Sir Crisp remains my mind. He had come to a west country *consultation* and after it was over I had be to show him the way back to the railway sta *return journey.* He was wearing, I particularl though it is nearly thirty years ago, a long coat with an astrakhan collar, and with step, charming manner, and distinguished entirely fulfilled the picture which my youth *tion had* conceived of a London consulti Later as dresser and house-surgeon I wa him better and like many others in this positio many kindnesses from him, but he was neve open his heart to more than a very few outs intimate *family circle.* Inseparable in his from his wife and daughter, to whom he w his work was his hobby, though he beca gardener and it gave him great pleasure that to cultivate a pink rose of much beauty whic the "Lady English", rose.

Gifted with an exquisite pair of hands, his when operating, in their precision and neatn joy to behold and an education to the you ut speculate what fields he might not have had he maintained the wide range of surgery ed in his early days and not narrowed his the main to the right lower quadrant of the Knighted but a short time after his 39th e came to have perhaps more national figures patients than any other surgeon of his genera- vas characteristic that he never talked about uished patients or mentioned their names in nversation, and this natural reticence perhaps hy it is not more generally known that he saved the life of Mr. Winston Churchill at the famous Dundee election in 1922. Appendicitis diagnosis, and counsels which might have advised postponing the operation until the Sir Crisp insisted on operating immediately hat night he removed a gangrenous appendix ted a tube. The patient, fractious at his ion, travelled to the North a few days later his drain still in situ fought and lost the election eel-chair. The great statesman has put it on t he returned without a seat, without prospects, ut his appendix.

V. H. R.

of Dr. Thomas Johnston English, Thomas Crisp s educated at Westminster School and St. George's where he held the William Brown scholarship. lifying in 1900 he was in the same year awarded ison scholarship of the Royal College of Physicians ears later the Jacksonian prize of the Royal College ns. In 1903 he obtained the F.R.C.S., and in 1904 ond. Besides his appointment at St. George's he e staffs of the Queen Alexandra Military Hospital, the Hospital of St. John and St. Elizabeth, King II's Hospital for Officers, the National Orthopædic and the Grosvenor Hospital for Women. An earlier ent was that of medical officer in charge of troops wer of London. During the 1914–18 war he served ing surgeon in France, and later, as consulting o our Forces in Salonika and in Italy. He was d four times in despatches. From 1918 to 1919 he mber of a War Office medical board. For these war he was appointed C.M.G. in 1917 and promoted he following year. He was also a knight-commander ler of George I of Greece, and a member of the order ava of Serbia. A Knight of Grace of St. John of n, he was a member of the chapter-general of r. After his retirement he published *Patients and itis* in 1946 and *Diseases of the Breast* in 1947. Sir glish married Miss Annie M'Leod, in 1905. She 946 and they are survived by their only daughter.

WILLIAM TURNER WARWICK

M.A., M.B. CAMB., F.R.C.S.

W. Turner Warwick, senior surgeon to the ex Hospital, died in the hospital on Aug. 21, ge of 61.

arted his medical studies in the medical school 1911 when he was an entrance scholar. At dge he had already obtained an honours degree hematics, and a half-blue for athletics. His -school career was distinguished and rapid, qualifying in 1915 he was awarded the Broderip ship. After a number of house-appointments he the R.A.M.C., serving in France. After the war, resident surgical officer at Leeds, where he came the influence of Moynihan, and at St. Mark's al, which started his life-long special interest in diseases. In 1920 he took the F.R.C.S., and two later he was appointed surgical pathological r at Middlesex, an appointment which profoundly ced his medical outlook. In the Bland-Sutton te of Pathology he worked under the director— e James McIntosh—and in close association with olleagues as Dodds, S. L. Baker, Lionel Whitby, carff. In 1923 he was appointed as a general n to the honorary staff of the hospital, a few years aking on in addition the department of proctology.

he outbreak of war in 1939 part of his work was erred with the Middlesex sector to Northwood tal. Owing to the simultaneous transfer of part of adiotherapeutic activities to the same hospital, his opinion began to be sought by his radiological colleagues on a wide variety of surgical problems connected with cancer. And at the time of his death he had built up a big reputation in this field. It was because of the same interest that he followed Sampson Handley as director of the diagnostic and advisory cancer clinic at Bournemouth.

D. H. P., to whom we are indebted for this memoir, writes: "Warwick's specialty was proctology. His written contributions to the subject were not numerous. but among them were two important articles on colostomy. He was an early convert to the simultaneous combined technique of abdominoperineal excision, and he had interested himself in the technique of preserving the anal sphincter in carcinoma of the rectum. A keen attendant at proctological meetings, in discussions he usually presented an original point of view which was always received by his colleagues with interest and respect. In wider fields he was one of the first in this country to recognise the new vistas opened for cancer surgery by the modern meticulous technique, a technique in its turn rendered possible by modern anæsthesia, supportive therapy, and chemotherapy. It was a matter for general comment among his colleagues how well cases of, for example, extensive resections of the mouth and jaw, extensive resections in the pelvis. or hind-quarter amputation used to do in his hands. Careful deliberate surgery was admirably suited to his temperament. The superficial and flashy were abhorrent to him. Colleagues consulting him on a difficult case could be assured of an opinion which was always profound and often original. His early training in mathematics had left him with an independent intellectual outlook, later conditioned by a deep understanding of pathological processes.

"Apart from proctology and cancer, he was particularly interested in varicose veins, and his book, published in 1931, on the rational treatment of varicose veins and varicocele is a classic. His work on varicocele provides the only satisfactory explanation yet given of the cause of the condition. He was also attracted by the problems of bone growth and gave a Hunterian lecture on the subject in 1942.

"He was always interested in students and the problems of teaching, but as teacher he was hindered by a hesitating delivery and a difficulty in putting his ideas into simple language. He was a good examiner, especially aware of the generally neglected problem of increasing the efficiency of examiners and examinations. In committee he was wise; at times his tendency to dig in until his point of view had been properly considered could be trying, but it was usually a point of view worth considering. His work as chairman of the medical committee of his hospital during the difficult period of transition from voluntary hospital to national hospital was outstanding.

"The most delightful of colleagues. he had a strong sense of humour and a shy but unaffected personality. As often with men of commanding stature, his gentleness. kindness, and simplicity of bearing were striking. Some men go on maturing all their lives. Turner Warwick was one of these. And when he was struck down he stood higher in the esteem of his colleagues than ever before."

Mr. Turner Warwick married in 1921 Miss Joan Harris who is also a doctor, and they had three sons and a daughter. His eldest son, like him, is a blue and a Broderip scholar.

JAMES FERGUSON

C.B.E., B.A., M.B. R.U.I.

Dr. James Ferguson, late medical officer of health for Surrey, died at St. Helier Hospital on Aug. 27. He was born at Muckamore. co. Antrim, in 1879 and educated in Belfast at the Royal Academical Institution and at Queen's College. A foundation scholar in classics, he gained an honours degree in arts in 1902, before qualifying in medicine in 1908.

His early training in public health was received in one of the best schools of experience in England—under Dr. J. J. Butterworth of Lancashire. From the post of chief assistant there he was appointed, in 1929, medical officer of health to the Surrey county council and he served in that capacity until his retirement in 1946. From that time he acted as a principal medical officer of the Ministry of Health, an appointment in which his long experience of hospital and health services was of great value. He was created C.B.E. in 1946, and was an honorary physician to the King from 1941 to 1944.

At the time of Dr. Ferguson's appointment to Surrey the transfer of municipal hospitals was taking place, and so the creation of a county hospital service was one of the most urgent duties of the new medical officer. He threw himself heart and soul into this work and became a leading authority on hospital planning. The St. Helier Hospital is a monument to his judgment and skill. The nurses' home has been named Ferguson House and it will be a memorial to his work. Dr. Ferguson was a keen supporter of voluntary organisations; in addition to his coöperation with the voluntary hospitals he devoted much of his time to service with committees, one of his special interests being the welfare of the blind. In his own professional sphere he served actively on committees dealing with hospitals and the welfare of nurses, and on the preventive medicine committee of the Medical Research Council. He was also a member of the medical advisory council of the Nuffield Trust and Foundation.

During the whole of the late war Dr. Ferguson lived and worked in the danger areas, giving his support and strength to the maintenance of hospitals and civil-defence services. His unhurried speed was always effective in promoting morale. He had no oratorical gifts, but his soft Ulster speech and gentle persuasive ways carried many a stubborn argument. He had a happy life, at home and at work. One of his constant joys was his relationship of mutual trust with the Surrey county council, and the years of unbroken friendship with his fellow officers in their public-health service. For seventeen years he was the devoted servant of a great local authority whose members regarded him with affection and respect.

Dr. Ferguson is survived by his wife and daughter.

Public Health

Control of Milk Production

REGULATIONS, made jointly by the Ministries of Food, Health, and Agriculture and Fisheries re-enact with amendments the Milk and Dairies Regulations, 1926–43, and the Milk (Special Designations) Regulations, 1936–48. These new regulations, which come into force on Oct. 1, give effect to provisions in the Food and Drugs (Milk and Dairies) Act, 1944, and the Milk (Special Designations) Act, 1949, in which the Government prescribed measures to improve the standard of purity of milk.

Under the Milk and Dairies Regulations, 1949, the Minister of Agriculture and Fisheries becomes responsible for the registration of dairy farmers and farms, the inspection of cattle on dairy farms, and the enforcement of the regulations on dairy farms (unless they relate to diseases communicable to man). Local authorities are still responsible for the provisions which apply to milk distributors other than dairy farmers, and for the registration of these milk distributors and of dairies other than dairy farms. Local authorities continue to be reponsible for the provisions relating to diseases communicable to man. As regards infected milk, the present powers are extended to enable a medical officer of health to stop the sale of milk, or to require milk to be diverted for heat-treatment, if there is evidence that it is infected with organisms pathogenic to man. A medical officer of health may also require milk to be diverted for heat-treatment if he has reasonable grounds for suspecting that it is so infected.

Under the Milk (Special Designation) (Raw Milk) Regulations, 1949, the designations authorised for raw milk are "tuberculin-tested" and "accredited." The use of the designation "accredited" will not be permitted after Oct. 1, 1954, while from Oct. 1, 1957, the designation "tuberculin-tested" may be used only for milk from an attested herd.

The Milk (Special Designation) (Pasteur- Sterilised [illegible] 1949, authorise th the special [illegible] steurised" and "s milk, and [illegible] priate licences are special designations "tuberculin-tested milk ised)" and "tuberculin-tested milk (sterilised) Oct. 1, 1950, pasteurised milk will be sold only or other containers, and from Oct. 1, 1951, th or other containers must be filled at the p premises.

Poliomyelitis

In the week ended Aug. 20 notifications poliomyelitis 273 ,(236), polioencephalitis Figures for the previous week are shown in

Multiple cases (poliomyelitis and polio together) were reported from the following London 35 (30), Bedfordshire 4 (2), Berkshir Buckingham 2 (2), Chester 6 (4), Cornwall 8 9 (1), Devon 9 (9), Durham 2 (3), Essex 10 (19), 5 (7), Hereford 2 (4), Hertford 3 (1), Kent 6 (6), 29 (23), Leicester 7 (4), Lincs Lindsey 3 (1), (10), Norfolk 3 (3), Northants 6 (2), North 7 (4), Nottingham 10 (4), Oxford 2 (1), Some Southampton 11 (13), Stafford 6 (4), Surrey 7 East 2 (5), Sussex West 3 (4), Warwick 4 shire 4 (2), Yorks, West Riding 50 (34), F Monmouth 2 (4).

The Ministry of Health draws attention previous remarks on tonsillectomy in ar poliomyelitis is prevalent: "Surgeons shou take the local prevalence of poliomyelitis int when considering the desirability of operat particular child." (See *Lancet*, July 30, p. 215.

Appointments

BAILIE, H. W. C., M.B. Belf., F.R.C.S.E.: surgeon, Co co. Derry, Northern Ireland.

BRODY, M. B., M.D. Sheff., D.P.M.: director of research, Hospital, Chichester.

BUTTLE, R. L., M.R.C.S., D.P.M.: consultant psychiatri Mental Hospital, Cambs.

CHRISTIE, A. L. M., M.B., PH.D. Lond., M.SC. N.Z.: sec pathologist, Norfolk and Norwich Hospital.

Notes and News

OVERDOSE OF AMPHETAMINE

rateful to Dr. Richard Worsley for the following

d 2$^{1}/_{4}$ years, was seen in the casualty department ls Public Dispensary and Hospital at 2.50 P.M. 2. The mother stated that one to two hours the child had swallowed some "energy" tablets son had acquired while serving in the Forces in e produced a small unlabelled tube which still en tablets. The full tube would have held twenty d the mother did not know how many the tube ned before the child got hold of it. The tablets 5 mg. amphetamine sulphate tablets, and some or analysis. A stomach wash revealed no trace of

The child appeared normal in all respects and was after the mother had been instructed to bring her if she noted anything unusual. At about 11.45 P.M. vening, the mother returned with the child, who veractive and would not stay in bed. Both had st of the 3 miles to the hospital. The child was o the ward. On examination no abnormality was cept overactivity and refusal to stay in bed. At she was given chloral hydrate gr. 5; she settled A.M. and slept until 4 A.M. At 6 A.M. this dose ed as the child was noisy and restless: she was at 8 A.M. and remained so throughout that day aking her food normally. After a further dose of 5 P.M. the child slept for an hour and then had a ht's sleep without further sedation. She was dis- om hospital next day, Aug. 24, quite normal in

d's condition did not cause any real anxiety to those

Some of the tablets were undoubtedly absorbed, nsomnia and excitability were compatible with etamine intoxication.

HE INDIAN MIDDLE-CLASS BUDGET

where the Indian middle class has suffered more om inflation since 1939 than any other section of unity. This is brought out by a report on family mong middle-class State employees of undivided ntly published by the central government. This a sample of 5000 persons drawing less than Rs. 500 1, subdivided according to residence in four major seven regional groupings. It gives an illuminating o their living conditions. Since it covers budgets 1946 it is somewhat out of date, but has the advan- ing on the conservative side inasmuch as the impact n is now more severe. It has the additional merit g Pakistan as well.

ng to this report average family incomes ranged 159 per month in rural Madras to Rs. 286 in Delhi, and allowances of the head of the family accounting % of the total. The average was depressed by the n of regarding all clerks—sometimes on a monthly y as low as Rs. 30—as members of the middle class. ess, it was found that only one in five of the Madrasis in five of the Delhi residents had surplus budgets. ntage of families in debt varied from 37% in the over 75% in Calcutta, the main causes of indebted- g sickness and marriage expenses. Resident depen- family earner ranged from 4·5 in Bombay city to har and Orissa, and non-resident dependents from adras to 1·4 in the United Provinces. The report that "expenditure was nowhere in reasonable dence with family income." Up to half the income t on food, milk, and fats. In housing government are far better placed than the general mass of people, they lived at an average density of 1·9–2·8 persons ; the cost of 10% or a little over in cities was not , but the quality was deplorable. Fuel and clothing 12–15% of the income. The miscellaneous residue % was expended on travel to work, children's educa- et and household requisites, postage, medical bills, rvants, laundry, share of a sweeper, &c.; outlay on pansupari, and holidays was relatively modest, yet s little margin left for a rainy day.

details make depressing reading. Nor is there any and immediate remedy. Continuous wage pressure s to the inflationary spiral. Permanent improvement of middle-class incomes, as indeed of others, can only come from greater productivity. Richer classes in India, apart from war-time profiteers, may be poorer than they were, but have greater scope for economy. Among the labouring poor there is undoubtedly distress; but the organised worker at least, aided by arbitration tribunals and cost-of-living awards, has to some extent been cushioned against the worst effects. The middle classes have standards of respectability to maintain and relatives and dependents to support. Among them government employees are in a comparatively privileged category, and the disabilities they suffer weigh more heavily on less privileged sections of the middle class.

MODERN PATTERNS IN CANCER RESEARCH

BIRD'S-EYE views of medicine are unsatisfactory unless the bird appointed is something of an eagle: for it takes a widely ranging eye to see enough of any field to survey it fairly. The New York Academy of Medicine's lectures to the laity have long been given by accepted eagles; and the set of six lectures published in *March of Medicine, 1948*,[1] are authoritative little surveys of the atom in civil life, food and civilisation, on being old too young, perspectives in cancer research, psychiatry for everyday needs, and the interrelation of pure and applied science in the field of medicine. All of these are worth reading, by doctors no less than by laymen, but in his discussion of cancer research Dr. Cornelius P. Rhoads, director of the New York Memorial Hospital, is perhaps specially adept in bringing an exuberant subject into perspective.

Cancer is rightly being examined in many ways at once: growth in general is being studied by chemical, physical, and biological methods, and so is the behaviour of cancers, without reference to cure; at the same time new methods of control and cure are being devised, and existing methods of diagnosis and treatment are being steadily improved. In spite of some equivocal evidence it is not possible to indict a virus finally as a cause of cancer in mammals; and even if it were, Dr. Rhoads asks, what would have been gained in terms of cancer control? The finding would only suggest, he thinks, that cancer might be contagious, and that patients should be isolated to avoid infecting others; and, since we know from experience that this is not so, we should not be much further on. In other words, discovery of the cause will not necessarily lead direct to the cure. Genetic studies have produced another kind of puzzle. X rays can cause mutations in strains of bacteria, amœbæ, moulds, insects, and even mammals; and they can cause mutation of normal cells into cancer cells. The unusual thing is that the mutant cancer cell is more competent than the ordinary cell—"viciously competent," as Dr. Rhoads puts it. "The cancer cell," he says, "is better able to survive in the environment in which it is born than is its parent strain of normal cells." Some dietary studies complicate the picture further: it has been shown that a dye which caused cancer of the liver in animals will only do so when riboflavine is absent from the diet. Again, a low-calorie diet reduces the incidence of cancer in mice; and this is true however the cancer is produced—whether spontaneously or by chemicals, or by ultraviolet light. The important factor seems to be reduced endocrine activity. Thus it may be (and microscopic studies support the suggestion) that cancer cells are formed and lie dormant for long periods, and they only become active when some change in the chemistry of the body fluids gives them their opportunity. Cancer control, then, might be a matter of preserving some chemical state which restrained the growth of cancer cells; and indeed we have found already that cancer of the prostate and the breast can be irregularly and temporarily controlled by altering the endocrine balance.

Some cancers can be controlled by direct chemical means: Hodgkin's disease, leukæmia, and lymphosarcoma, nowadays regarded as cancers of the blood-forming system, respond to two different groups of compounds—the nitrogen mustards and urethane. Or a radioactive substance may be used to attack the cancer from inside; thus thyroid cancer has been treated with the radioactive isotope of iodine. Dr. Rhoads suggests that we need intensive study of the synthesis and metabolism of steroid hormones resembling those formed by the sex glands and the adrenals; study of chemical agents which are now weakly active in controlling cancer, and an empiric search for new ones; and the pursuit of new isotopes capable of killing cancer cells without forming dangerous concentrations in normal cells. Meanwhile, thanks largely to better and earlier surgical intervention, and advances in radiotherapy, the death-rate for cancer adjusted for the age of the population "is clearly and sharply on the down grade." The whole prospect is much more hopeful than it used to be; pieces of the jig-saw are being collected at a prodigious rate, and one day will inevitably fit together.

Society of Apothecaries of London

At recent meetings of the court of assistants, over which Prof. E. C. Dodds, F.R.S., the master, presided, Mr. Duncan C. L. Fitzwilliams was elected master from Aug. 24, and Dr. Frank Howitt and Dr. G. Roche Lynch were elected wardens. Dr. J. F. Carter-Braine took his seat on the court of assistants.

The following examiners were sworn in: Mr. Anthony Charles and Mr. Norman White (midwifery); Mr. Paul Haas, D.SC. (chemistry). Dr. Thomas Hunt was appointed examiner for the diploma in industrial health.

R. M. Haines was clothed by the master with the livery. The following were admitted to the freedom of the society by redemption:

F. C. Blaaberg, L. H. Lampitt, Sir Stanford Cade, R. T. Brain, K. J. Franklin, Kenneth Robson, J. C. N. Wakeley, E. R. Boland, H. B. O. Cardew, Sir James Walton, A. J. Walton, E. J. Crisp, A. E. M. Woolf, G. H. Hogben, E. T. D. Fletcher, Edith C. Hudgell, G. R. M. Cordiner, Sir George Aylwen (Lord Mayor), S. W. Davidson, N. R. Barrett, C. B. Perry, W. P. Cleland, J. G. Scadding, A. W. Spence, P. R. Allison.

The following were granted the diploma in industrial health on examination:

J. A. Herd, C. N. D. Cruickshank, C. Crowley, G. G. Mathew, W. G. White.

The diploma of L.M.S.S.A. Lond. was granted on examination to the following:

H. T. H. Beach, J. L. Jarvis, D. Redpath, G. E. Hanks, F. W. Retief, M. P. Cardew, K. C. Horrocks, E. M. Tiger, H. V. White, M. P. M. Coupland, R. J. Aspinall, C. J. G. Menzies, C. R. May, M. C. H. Jackson, H. E. G. Dyer, F. Walton, F. E. Bramwell, E. R. Goodall, D. J. Joubert, G. B. Stephenson, W. G. Burvill Holmes, G. T. Cecil, G. A. R. Giri, P. B. Poole, A. K. Kantarjian, L. Kader, J. D. Morris, C. T. Jones, E. W. Melia, M. C. Gilbert, A. S. Murad.

Edinburgh Post-Graduate Board for Medicine

On Tuesday, Sept. 6, at 4.30 P.M., in the anatomy theatre of Edinburgh University, Prof. D. V. Davies is giving a lecture on Synovial Membrane in Health and Disease.

Scottish Intelligence Survey

Speaking in Oxford at a summer school of the National Union of Teachers, Sir Godfrey Thomson, D.SC., professor of education in the University of Edinburgh, announced that the Nuffield Foundation would finance the first 5 years of the 20-year plan for testing the intelligence of Scottish school-children. The children are to be selected from among those born in 1936 in every type of family.

Royal Photographic Society

The annual exhibition of this society will be held at 16, Princes Gate, London, S.W.7. This year the exhibition is to be divided into two parts. Pictorial, colour, and stereoscopic exhibits will be shown from Sept. 9 to Oct. 2, and scientific, nature, record, and technical exhibits from Oct. 8 to 26.

National Association for the Prevention of Tuberculosis

A joint meeting of the association and the Society of Medical Officers of Health will take place in B.M.A. House, Tavistock Square, London, W.C.1, on Thursday, Sept. 15, at 2.30 P.M., to discuss social and aftercare arrangements by local health authorities under the National Health Service. The following will open the discussion: Sir Allen Daley, Dr. G. W. H. Townsend, Dr. W. Alcock, Dr. Neville Irvine, and Miss Anne Topley.

Preventive Dentistry

The Ministry of Education has set up a Working Party to direct and organise an investigation on the prophylactic effect of the local application of a solution of fluorides to school-children's teeth. The members are: R. Weaver, M.D., F.D.S., Ministry of Education (chairman); E. R. Bransby, PH.D., Miss J. R. Forrest, L.D.S., and W. G. Senior, PH.D., F.D.S., Ministry of Health; G. J. Parfitt, M.R.C.S., L.D.S., department of preventive dentistry, Eastman Clinic; B. R. Townend, F.D.S., West Riding local education authority; W. Ritchie Young, F.D.S., London County Council; and A. T. Wynne, M.D., B.D.S., Ministry of Education (secretary).

King's College Hospital Medical School

Sir Hugh Cairns will deliver the inaugural ad
opening of the 120th session of the medical scho
Hill, London, S.E.5, on Friday, Sept. 30, at 3 P

A Second Pair of Glasses

DYSMENORRHŒA *

A. J. WRIGLEY
M.D. Lond., F.R.C.S., F.R.C.O.G.
L PHYSICIAN AND LECTURER ON MIDWIFERY AND
ES OF WOMEN, ST. THOMAS'S HOSPITAL,
LONDON

ORRHŒA seems to be as old as the hills. It ally thought to be due to obstruction and d by abdominal massage and cervical dilatation gies or with pessaries. Soranus (A.D. 98–138) rest, massage, fomentations, compresses, douches, with massage and remedial exercises he menstrual periods. Congestive dysmenor- ears first to have been suggested by Aetius th century, and membranous dysmenorrhœa ribed by Morgagni in 1779. From ancient atively recent times the theses of Hippocrates nus were accepted almost in their entirety; the nineteenth century no writer did much repeat them.

Simpson described an operation for the relief orrhœa in which he cut the wall of the cervix ally with a hysterotome. In 1872 Hegar, nd Battey, in August, each performed a bilateral omy (normal ovaries were removed) to cure rhœa.

edicinal treatment of dysmenorrhœa in the h century included valerian, oxide of zinc, m, prussiate of iron, quinine, ergot, salicylates, of muriate of iron, tincture of guaiacum, s, ammonium bromide, *Veratrum viride*, bella- *Sanguinaria canadensis*, ammonium acetate, m, cerium oxalate, viburnum, and ulakambal. ments tried in recent times are quite as varied. g to the *Quarterly Cumulative Index Medicus* and 1947, these have included acetylcholine, Edrisal,' endometrial extract, resection of the nerves, genital hormones, 'Pavatrine,' l,' phenylpropylethylamine, stem pessary, mones, 'Donnatal,' resection of the superior ric plexus, disinsulised pancreatic extract, rcises, ephedrine, vitamin-B complex, loosening contractures, pregneninolone, and deproteinated ic extract. This second list well illustrates the onfusion in the treatment of dysmenorrhœa.

CLASSIFICATION

(1938) wrote: "... Dysmenorrhœa ... has been ed into primary and secondary, essential and atic, spasmodic and congestive, intrinsic and , ovarian and uterine, obstructive, mechanical, tory, habitual, temporary, neuralgic, accidental, gical, vagotonic, &c." He criticised the terms y" and "secondary," and "intrinsic" and ic," because they imply two types of dysmenor- e in which the fault lies in the uterus, and the which the fault lies outside. The uterus should lamed, for in both types the hypercontraction ordination, which cause spasmodic dysmenor- d the vascular imbalance which is the foundation stive dysmenorrhœa, are secondary to nervous nonal abnormalities. Davis almost absolved us and its possible abnormalities in development, ize, &c., from being directly associated with the ion of pain. Nevertheless, since classification kind was essential, he adopted in this book the natic division of "spasmodic" and "congestive," e pseudopathological one of "primary" and lary."

Blair Bell (1934) had different ideas about the classification of dysmenorrhœa; he wrote:

> "Such classifications as 'spasmodic' and 'congestive' should be cast aside, for they are evasive and futile. The advantages attaching to a pathological classification of disease have never been better shown than in the subject under discussion, wherein a proper pathological knowledge has placed the methods of treatment on a scientific and satisfactory basis."

In spite of this he made the very error he deplored, by dividing his subject into "intrinsic" and "extrinsic."

"SPASMODIC" DYSMENORRHŒA

It may be thought that the spasmodic type of dysmenorrhœa is universally accepted and there can be no possibility of doubt about its existence. Has not the muscular spasm been seen at operation? Has it not been demonstrated radiographically by Schultze and others (cited by Davis 1938; p. 45)? And have not records been made of the variations in uterine pressure which coincide with the contraction and relaxation of the organ? Have not these contractions been demonstrated to be synchronous with the pain?

To these questions I would reply with others. Has the actual spasm been observed at operation? Could not the pale bloodless areas, supposed to be bloodless because the spasm has driven all the blood out of the vessels and the tissues, be due to ischæmia produced by intense vasoconstriction? Do the radiograms of Schultze really demonstrate spasm? What is the effect of the presence of a small hydrostatic bag, acting like a foreign body, within the uterine cavity? Is it certain that by this means an accurate record of the strength and frequency of the muscular contractions is obtained? Is there *no* chance that the presence of the foreign body influences the results obtained? I know that Moir (1934) has shown different readings in patients who have and who do not have spasmodic dysmenorrhœa. But still I wonder.

NERVOUS CONTROL OF UTERUS

When we consider the nerve-supply to the uterus, and the ways in which muscular spasm may be produced, the picture becomes even more confused. In the first place, spontaneous strong rhythmic contractions of the uterus have repeatedly been observed when it is separated from all its nerve-supply. This, however, does not mean that the uterine contractions are not affected by nervous influences. Though many believe that the uterus possesses two sets of autonomic nerves, others are most emphatic that the existence of a parasympathetic supply is far from proved, and insist that this question is still sub judice.

Be that as it may, we must now ask what is the action of the sympathetic nerve-supply on the uterine muscle. Reynolds (1939) cites Cyon, an early worker, as having observed that he failed completely to obtain either motor or inhibitory effects from stimulation of the peripheral ends of the cut sacral nerves—a fact later confirmed by Langley and Anderson (cited by Reynolds 1939; p. 272) and many others. Cyon did note, however, that contraction of the uterus resulted from stimulation of the central end of the cut sacral nerves; this effect had been produced via the pelvic plexus. The only motor response from stimulation of the peripheral ends of the cut sacral nerves was contraction of the rectum and bladder. Section of the presacral nerves, leaving the sacral innervation intact, cut all the sensory pathways from the uterus, and Reynolds concluded that the sensory nerve connexions of the uterus passed to the central nervous system by way of the abdominal sympathetic system.

Hitherto no distinction has been made between the character of the motor responses of the uterus when one

---

on a postgraduate lecture given at the Royal College of etricians and Gynæcologists on Nov. 19, 1948.

group of nerves is stimulated, and the response of the myometrium when other components of the uterine innervation are stimulated. So far as we have gone, the only assumption that we could make is that the whole uterus contracts when any of the nerve groups supplying it is stimulated. For many years, however, it has been suggested that different effects could be obtained in different parts of the uterus by stimulation of this, or that, group of uterine nerves. Nearly 100 years ago it was suggested that stimulation of the nervus erigens caused contraction of the longitudinal fibres of the body of the uterus, and at the same time by inhibition caused relaxation of the cervix, whereas stimulation of the presacral sympathetic nerves produced exactly the opposite results. Salgannik (1935) suggests that the body of the uterus is innervated mainly through the hypogastric nerves, and the cervix through the sympathetic. Several workers failed to obtain any muscular response from stimulation of the peripheral ends of the cut sacral nerves, and in Reynolds's (1939) own words: "Hypotheses which are based upon the assumption that the uterine musculature is innervated by the sacral autonomics are without merit, so far as our present understanding of the innervation of the uterus is concerned."

To add to our confusion, it appears that different motor responses may be expected according to the level in the sympathetic chain at which this stimulation occurs, and that all effects of stimulation, however and wherever brought about, may be entirely different in the non-pregnant uterus and in the pregnant uterus.

This brief and confusing review of the neuromuscular relationship of the pelvic nerves and uterine muscle has not been produced in any spirit of criticism of those many workers who have spent an enormous amount of time and painstaking labour in attempting to solve an obviously extremely difficult problem. We have seen that the uterus can contract, so to speak, on its own; that there are described two sets of nerves, sympathetic and parasympathetic, and that the existence of the latter is disputed; that opinion is by no means unanimous about the response to stimulation of the peripheral or of the central ends of cut nerves; and that any apparent constancy in any response may be dispersed if the nerve is stimulated at different levels, and altered completely according to whether the uterus is, or is not, pregnant. My only conclusion—and this I emphasise is the opinion of an onlooker—is that I am quite unable to accept, in the light of present knowledge, any relatively simple explanation of the causes, routes, means, call it what you will, of uterine contractions, spasms, colics, or relaxations; nor am I at all convinced of the production of uterine pain by spasm.

Pain

The problem is not tied up only with a nerve stimulus and its hypothetical response. Leriche (1937) and many others have told us that other *and very important* factors must also be considered. We are dealing with living people and must take into account the variable reaction to pain exhibited by different people, and the state of mental or physical health of the person at the time.

We are only beginning to study and to understand what may be called the physiology of pain. The further our researches extend into this subject the greater appear the fallacies of preconceived ideas. The part played by vasoconstriction and vasodilatation in the production and relief of pain is assuming an ever-increasing importance. For instance, any alteration in the condition of the peripheral circulation by means of excision of the perivascular nervous plexus, or by its infiltration with procaine, can be made to abolish the pain in a limb, the distribution of which pain appeared typical of some particular sensory nerve. I am sure we will hear much
more about the association between vasoconstri
dysmenorrhœa in the near future.

Endocrine Glands

Recently pointers have been given to the par
in the production and diminution of pain by the
glands, especially the suprarenal glands and th
in the constriction and dilatation of blood-v
at the same time the possible influence of th
chemistry, as suggested by the painful contrac
associate with a diminished blood-calcium conten

CONGESTIVE DYSMENORRHŒA

Congestive dysmenorrhœa is now divided into
and secondary. The primary type presumes a
primary congestion. I do not believe that th
or that it is a possible cause of the pain.
describe the condition say that it is charact
severe pain felt during the first two or three
menstruation, and at the same time the amount
ing is usually greater than the normal.
statements taken together do not, and never w
sense; for, if there is congestion it will be
by bleeding, which immediately relieves tensio

RELATION OF DYSMENORRHŒA TO TOTAL CONDITION

Let us recall an easily overlooked fact.
must still embrace the whole subject; the
tendency to specialisation the more likely is t
forgotten. Thus, the very fact that all teachin
possess, in addition to many other special dep
a department of gynæcology inevitably influe
students, and (I am sorry to say) many of their
also, to look first, or perhaps only, to the pelv
for the explanation of any or all of the sympt
appear to originate from some disorder of the
of the ovaries.

My teaching on any disorder of menstruation
amenorrhœa, scanty menstruation, menorr
dysmenorrhœa, is that questions must be ask
search made to find out whether the symptom
likely to result from some general medical
rather than some intrapelvic abnormality. Th
association between amenorrhœa and such c
as diabetes, hyperthyroidism, an acute febri
an operation, mental shock, and a complete c
mode of life is known to all of us; but it is of
looked. Likewise, we all have seen menorr
metrorrhagia accompany such diseases as t
anæmias, thrombocytopenic purpura, and seve
tension. We may have been surprised and gra
the rapidity with which the symptom disappea
a patient has taken our advice that to look afte
and family and to follow an arduous employ
beyond her strength and that her outside wo
be discontinued, at least for a time. How eas
ignore the patient's medical and social bac
and to search for and find a hypothetical disord
position, size, or shape of the uterus! If this sor
can happen with concrete symptoms, such as
rhœa and menorrhagia, I am sure the temp
look to the uterus or its nerve-supply for the
the less definite symptom of dysmenorrhœa i
great or even greater.

ABNORMAL TISSUE

Pelvic Endometriosis.—Dysmenorrhœa does ac
endometriosis, a condition which, though un
is not very rare. There is a definite age-incide
the pain, which may be noted for a few days b
onset of menstruation, reaches its maximum d
first three days of the period. Abnormal physi
are found on examination.

Uterine Fibroids.—In a similar manner dysme
may be found in association with a uterine fib

PELVIC INFLAMMATION

congestive dysmenorrhœa accompanies any r subacute inflammation in the pelvis. Again of affairs is uncommon but certainly not rare o be overlooked. The pain at the time of ds may be the dominant symptom about which nt seeks advice. It too bears a definite ip to the period. Usually starting some days e period is due, it reaches a maximum just e onset of the period and is often relieved by the menstruation. It is as if a state of tension is by the addition of the premenstrual and ical hyperæmia and relieved by the loss of blood. in is something definite in the history, and physical signs should be apparent on ion.

ENDOCRINE IMBALANCE

w leave the certain known demonstrable causes to consider the probable but slightly less definite rate to the student and perhaps to the teacher ditions that appear to be closely associated with rrhœa.

sia or Imperfect Maturity of the Uterus

must only be diagnosed on definite evidence from the history, symptoms, *and* physical d not from the history, symptoms, *or* physical We are not justified in diagnosing hypoplasia history alone, or on some possible and usually isputable physical abnormality. The dysmenorust have existed from the *onset of menstruation*; t is usually at a later age than usual; and the between the periods is rather longer than normal ot constant. Menstrual loss tends to be scanty ompanied by a variable amount of pain. The may be of normal intelligence and mental standard normal, or definitely subnormal. Physically, eral development, especially of all secondary racteristics, is incomplete; if this is not so, e no right to make the diagnosis and no basis for the appropriate treatment. Breast developpoor, and hair distribution incomplete. Rectal ation, or vaginal examination under anæsthesia, how that the uterus is definitely not fully ed.

Bell (1934) and many others emphasise the tion between the imperfectly developed uterus smenorrhœa, but they did not (or do not) draw n to the fact that the small uterus is only one station of a much more important general state mplete maturity. It may be that the imperfectly ed uterus has a shorter cavity than is normal, acute flexion is a sign of imperfect development, s far wiser not to direct the attention of the patient, e student, to these local and relatively unimportant rities, but rather to emphasise the more definite clinical picture.

e condition that has been described is thought resent, some benefit to the patient and consequent from her symptoms may be expected from the istration of œstrogens. Thus, a fairly large dose—ilbœstrol 1 mg.—should be ordered and the patient ted to take one tablet twice a day from about the o the 27th day of the cycle for about three months. treatment is going to help, the success will soon parent, and for the second three months the dose e halved, and thereafter treatment discontinued. gens are not given in the first half of the cycle se cases, owing to the risk of their suppressing tion, an event not to be desired in a young and tially healthy girl. An initial freedom from pain first few months of menstruation in these cases een thought to be due to the fact that ovulation is absent to begin with, but this suggestion is entirely hypothetical.

Membranous Dysmenorrhœa.—The second type of dysmenorrhœa that may with reasonable certainty be associated with dysfunction and imbalance of the secretions of the endocrine glands is membranous dysmenorrhœa. Morgagni (cited by Davis 1938; p. 128) described this nearly two hundred years ago, and Beckwith Whitehouse (1926) drew our attention to its importance and nature in many papers and in his book on gynæcology. The patient is usually a healthy active girl or woman whose early years of menstruation were usually free from pain. For no known reason severe and intermittent or persistent dysmenorrhœa develops, colicky pain being felt on menstruation. Occasionally the patient may associate the most severe pain with the expulsion of clots or lumps.

Whitehouse showed that, whereas the expulsion of a complete endometrial cast of the uterus was rare (the presence of this cast was previously necessary for the original diagnosis of membranous dysmenorrhœa), the endometrium was expelled much more often in several large pieces of tissue. This tissue examined microscopically, showed definite pathological changes: the endometrial membrane was much thicker than normal, and the increase in thickness was due to a considerable overgrowth of the compact layer, the so-called premenstrual decidua. The growth of this tissue is under the control of the corpus luteum, and this association had been observed at operation for some years before its exact nature was understood.

Ordinary antispasmodic drugs, or simple cervical dilatation and endometrial curettage, had been of little help to these patients, who often were treated by hysterectomy or later by X-ray sterilisation. In the knowledge that œstrogens lessen the activity of the anterior part of the pituitary gland and by this means may decrease the production of luteinising prolan, the suggested treatment is again œstrogen therapy. The dosage is, as before, on the large side, but the time of administration in the cycle is slightly different, in that treatment should start rather earlier in the cycle, about 9 or 10 days after the onset of menstruation, and should continue until the 26th or 27th day.

I believe that a large, even a very large, number of patients should have come under this category who have been erroneously diagnosed and treated as cases of spasmodic dysmenorrhœa. The menstrual loss may be assessed as normal or may be obviously excessive; it is never scanty. Whitehouse likened this condition and its symptoms to a pseudo-abortion, and his comparison is probably accurate. But, having reached this satisfactory state of affairs as regards our accepted pathology of this type of dysmenorrhœa, we must remember that it is certainly possible for a patient to pass an endometrial cast, abort an ovum, or even give birth to a full-sized baby at term without experiencing any pain whatever; but such events are rare.

Other Conditions of Endocrine Imbalance

As regards the other endocrine glands of the body, all have been in their turn singly or severally blamed for their part in the production of dysmenorrhœa. Thus, the pars anterior in the pituitary gland in its control of the ovarian cycle has been an obvious target for attention, as also has the posterior part concerned with the production of pituitrin, whose oxytocic properties provide an easy explanation for spasm. The enlargement of the thyroid gland in the few days before menstruation has suggested a possible relationship to dysmenorrhœa. The production of muscular spasm, following a lowered blood-calcium level, immediately suggested a reason for implicating the parathyroid glands. Even the thymus gland (cf., the use of 'Thymophysin') was thought to have a tonic effect on the uterine muscle. All these glands have had their day, and doubtless that day will return again and again as the years roll by, but I am pretty certain that it is unlikely that any one of them will be found to be responsible for dysmenorrhœa.

PSYCHOGENIC FACTORS

Davis (1938) devoted only three pages in his book to the emotional aspect, and as few lines are allotted to it in some modern textbooks on gynæcology. It is generally agreed that the psychogenic factors must be considered, but there is no general agreement about their importance. I suggest that at present an entirely insufficient consideration is given to this aspect of dysmenorrhœa by most doctors, whether they be in general or specialist practice; and the specialist seems to be the greater sinner. All of us must have seen cases where the psychogenic factor was the obvious cause of the dysmenorrhœa—e.g., the patient who is married and anxious because no pregnancy follows normal married life. The folly of a failure to recognise the true state of affairs, and in consequence the treatment of the wrong condition, needs no emphasis.

In every case of dysmenorrhœa a careful inquiry on common-sense lines into the social, domestic, economic, occupational, and habitual background should be made, and in my experience this often, and without any special training in the higher arts of psychology, brings to light some circumstance of importance. I think it nothing short of a tragedy that the teacher should try to fit each case of dysmenorrhœa into the pigeon-holes labelled spasmodic, congestive, and membranous, and I use none of these three labels. There is no need to accept the Freudian outlook, which would regard each case of dysmenorrhœa as the expression of some repressed sexual instinct, but a proper appreciation of the neuropsychic factor is essential to the proper understanding and management of dysmenorrhœa.

Maleducation

Occasionally we meet the case of a girl whose dysmenorrhœa seems to be the result of what can only be termed maleducation. She is, in my experience, always an only child and always accompanied by her mother, who has also had dysmenorrhœa. From the onset of menstruation the menstrual period has been given undue importance. The girl has stayed away from school, and may even have been kept in bed for a short time. I believe that these patients consciously, or subconsciously, welcome this relief from the daily round and are genuinely resentful of any alteration of the routine. Any suggestion that less attention be paid is certainly not at all welcome, and the management has to be most carefully undertaken. The mother needs quite as much handling as the daughter, and all sorts of legitimate subterfuges can be used.

Debility

Lastly, the discomfort of menstruation can easily be turned into a severe pain in any patient who is suffering from true debility, whether this be the result of illness, overwork, or worry. The treatment here is the treatment of the cause, and again I emphasise the fatuity of any treatment of the pelvis, or in fact of any treatment whatever, that ignores the cause. And yet how often this happens; indeed we may ask how often we ourselves have done this.

I have not mentioned the pin-hole os, the uterus with a kink, congenital retroversion of the uterus, sclerocystic ovaries, and many other possible and impossible abnormalities.

TREATMENT

The subject of dysmenorrhœa, and therefore the patient who complains of this symptom, should be approached with the knowledge that we are almost always dealing with a *symptom* and not with a that we should *pay far more attention* to the background, and that we should make a *examination as well* as a pelvic examination.

Antispasmodics.—The treatment of obvious dysmenorrhœa is obvious; we must treat th which is often missed altogether. The is that of the young woman who is apparently in physical health, mentally sound, and prostrat month with "spasmodic" dysmenorrhœa. I already stated that I am perfectly certain th diagnosis is made far too often and too readily. however, even I am forced to make it, how do I treat the condition? Usually the patient has tried, and failed, to get relief by the use of th spasmodic drugs, such as aspirin, 'Veganin,' &c.; but that does not mean that she should them altogether.

Attention to Bowels.—It is useless to treat rhœa in the presence of chronic constipation; treatment of constipation does not consist in the of this, that, or the other purge, aperient, or Often the pain at menstruation has gradually as the bowel action slowly returns to normal.

Physiotherapy.—The next line of attack is to aid of the physiotherapist; by this I mean patient is instructed in remedial exercises and is vised regularly in their performance. Davis dismissed the successes claimed by such adv this method of treatment as Ewing, Bell, and Par stating that they probably erred on the side of and that the great majority of cases treated relatively slight. This may or may not be true—no uncritical assessor of physiotherapy—but I hav and I continue to see, really severe cases of " dysmenorrhœa relieved completely of pain by of treatment. I would use the word "cured," dare not do so. Occasionally this method fails, now only a few cases remain and they are treat cervical dilatation.

Cervical Dilatation.—Twenty years ago over dilatation operations were performed each ye St. Thomas's Hospital for "spasmodic" dy In the last ten years, not 10 cases have been so in any one year, and in 1946 only 3. This may be to a fall in the number of cases presenting them at hospital, the success of other methods of inv tion and treatment, or the fact that our the subject has become unpopular or out of date, the result that the patients have gone, or have sent, elsewhere. I am sure we may dismiss the and I suggest that the second suggestion is probab most important.

Presacral Sympathectomy.—As a team, we have formed a presacral sympathectomy but five time this is only because we have not had any nece consider its more frequent performance.

Other Treatments.—In the treatment I have outl I have not mentioned such methods as helioth diathermy, ionisation, protein shock, vitamins, and m psychotherapy, radiotherapy, or hysterectomy.

DISCUSSION

Some writers on the subject believe that the expl tion of dysmenorrhœa is most likely to be found in orders of the endocrine glands. One probable ex of this is that overgrowth of the corpus luteum pro too great a quantity of progesterone, which leads endometrial membrane possessing a thick compact l of decidual-like tissue, the expulsion of which in p or in toto, may be accompanied by colicky pa contractions of the uterus. Another probable ex is dysmenorrhœa associated with imperfect develop-ient and of her uterus, and apparently relieved gen therapy.

lleged examples are far more difficult to accept. ıce, on the assumption that œstrogens sensitise e muscle to the action of the oxytocic principle sterior part of the pituitary gland, and that one has the opposite effect, it has been suggested es that too much œstrogen in circulation causes rhœa. It has often been noted, however, that ›pathia hæmorrhagica, where there is an d overproduction of the follicular hormone, ıotoriously absent, even though strong con- of uterine muscle may be observed during sion of the blood-clots. Progesterone therapy elief of dysmenorrhœa has often been advised l, and the results, on the whole, have been ting.

ssible relationship between other ductless glands ful uterine contractions is based on so flimsy ion as not to deserve serious consideration.

we come to associate endocrine dysfunction listurbance of the innervation of the uterus, into very deep waters. The large ganglion the paracervical ganglion of Frankenhäuser e after removal of the ovaries and regenerate rogen therapy. This phenomenon may reconcile nologists and the endocrinologists.

is undoubtedly some truth in all these theories estions; but when the few certain causes of l pain, such as inflammation, can be excluded, no generally acceptable explanation for the g cases. If we agree on this point, we shall be e to make serious mistakes by labelling these either "spasmodic" or "congestive." If is we, our pupils, and our patients will receive her stimulus to concentrate on the pelvic organs ost likely site of the cause. With every succeed- there will be less and less likelihood that the as an individual human being, will be considered ored with a view to finding some physical and/or d (I put them in this order lest I be thought biased, but I believe they should be the other nd) abnormality or upset that may have some perhaps a most important one, on the symptom. let me earnestly plead that this general examina- ould always be performed carefully and not orily before attention is directed to the pelvis. e a pelvic examination is necessary—even when ve we have discovered some abnormality in the which seems to be the probable, or perhaps cause of the pain.

eve my teachers, even though they were ignorant scoveries made in the last twenty to thirty years, y generation a more sensible and wholesome n and outlook on dysmenorrhœa than is given teachers today. Meigs and Sturgis (1947) devote 3 pages on the treatment of dysmenorrhœa to l sympathectomy. What impression can be when this article is read by the practitioner or ? There is only one possible answer, and that the treatment of dysmenorrhœa is presacral ıectomy, and this is becoming the usual answer mination candidates. Indeed this presacral ıectomy seems to be the sole treatment adopted American clinics, and seems likely to become er home before long. If this happens we shall g backwards—not forwards. Let us rather, as Bell exhorted his readers, "temper surgical with physiologic mercy."

MERCURY POISONING FROM FINGERPRINT PHOTOGRAPHY

An Occupational Hazard of Policemen

JOHN N. AGATE
M.A., M.D., Camb., M.R.C.P.

MONAMY BUCKELL
B.Sc.

From the Department for Research in Industrial Medicine (Medical Research Council), The London Hospital

IMPRESSIONS of fingers have been found on relics from ancient civilisations, but there is no reliable evidence that they were used for identification. Purkinje (1823) was the first to classify fingerprints, but no immediate use was made of his ideas. In 1880 Sir William Herschel described how, as an administrator in the Hooghli district of Bengal, he had been using fingerprints for about twenty years as a safeguard against impersonation and repudiation of signatures. Nevertheless, it was Faulds (1880) who first suggested that fingerprints might be used for personal identification, particularly of criminals. In the next decade both Faulds (1894) and Sir Francis Galton (1892) separately evolved systems of classification. Then Sir Edward Henry, formerly of the Bengal Police, adopted Galton's classification and began systematic detection by fingerprints; in 1901 he set up the finger-print bureau at New Scotland Yard.

METHODS OF DEVELOPING LATENT FINGERPRINTS

Police methods of recording and comparing fingerprints have not greatly changed since they were first used. Prints are still taken from the fingers of suspects by covering them with printer's black ink and pressing or rolling them on cards. Dark coloured powders have occasionally been used. The process in either case is simple and without risk. Detection by fingerprints depends on the comparison of such inked impressions with latent fingerprints left on furniture, doors, or movable objects at the scene of a crime. Such prints, left by the film of sweat and grease on the finger-tips, have often to be developed and photographed for greater ease of comparison and recording. Developing is done by applying a finely divided powder—a light-coloured powder on a dark background, or a dark powder on a light background—with a soft flat squirrel-hair or camel-hair brush, and the excess is brushed or blown off. Insufflators have been used, but with less success. The powders used in the past have included aluminium, willow charcoal, acacia black, lampblack, powdered graphite, and white lead. The last named was the cause of a case of chronic lead poisoning reported by Nyfeldt (1937).

This man had worked for the police in Denmark for twenty-six years developing fingerprints. He was thought to have inhaled the white-lead powder. Six years after starting to use it he developed colic and neuritis. Twenty years later, while still using it, he suffered from arthralgia and swelling of one knee, and punctate basophilia was found in his blood.

The powder most commonly used in British and United States police forces is mercury-with-chalk or grey powder (hydrargyrum cum creta *B.P.*), prepared in the usual way by triturating one part by weight of metallic mercury with two parts of chalk in a mortar. This powder seems to have a particular affinity for the sweat-formed latent prints, and produces a good image for photographing.

A competent police authority estimates that 90% of all developing of latent prints in Great Britain is now done with this powder.

Police forces in this country do not all place the same reliance on detection by fingerprints. In most forces detectives are required to undertake fingerprint work as a minor part of their duties. The Lancashire Constabulary, however, sets particular value on such techniques, and employs a body of men who are specially trained for fingerprint duties. They are members of the criminal investigation department who also perform ordinary detective duties.

The men with special training consist of a detective chief inspector and some 32 detective sergeants and constables. At their headquarters some men search files of prints, while others develop and photograph latent prints on small objects brought in. The remainder of the men are stationed at scattered points throughout the county and are called in to take fingerprints at scenes of crime. With such specialisation it is inevitable that these men should be working with grey powder for long periods —certainly for several hours each week—since all breaking-in offences in the area are investigated in this way as a matter of policy.

The powder is dry and finely divided. It is applied liberally from a well-loaded brush. The brush itself is often cleaned by rubbing against a convenient door-post, and powder rises in a cloud. At the end of the operation excess powder may be left lying about in the room while investigations are going on. Some detective sergeants and constables wear gloves at work, but none wear dust-masks. Grey powder has been used in this way in the Lancashire Constabulary since 1936. Recent consumption of it there had been at the rate of 5 lb. a month, and the risk of chronic mercury poisoning could not be ignored.

MERCURY AS OCCUPATIONAL HAZARD

Poisoning by metallic mercury probably dates from its first use as a therapeutic substance over two thousand years ago (Almkvist 1929). It has been known as an occupational hazard since Roman times, when quicksilver was mined in Spain. Mercury amalgams were used in refining precious metals and in fire-gilding in the Middle Ages, and their use gave rise to tremors. In the nineteenth century there were serious outbreaks of mercurialism in makers of mirrors and among workers in the felt-hat industry (Hamilton 1925), where the condition is known as "hatters' shakes." More recently the disease has been studied in the hatters and hatters' furriers trades by Hamilton (1921) and Neal et al. (1941), and among thermometer makers and chemical workers by Buckell et al. (1946). Other trades in which there is a risk of mercurialism are the recovering of the metal from ore, the manufacture and servicing of electric meters, the making of surgical dressings containing mercury salts, the bronzing of field-glasses, photo-engraving, the making and use of laboratory apparatus, and the preparation of pharmaceutical products containing mercury.

SYMPTOMS OF MERCURY POISONING

Stomatitis.—The foremost symptom in the early outbreaks was stomatitis, with retracted spongy bleeding gums, loosening of the teeth, fœtor oris, and salivation. This last symptom gave rise to the name of "salivation cures" for the energetic mercury inunction practised by Sydenham and later by John Hunter (Almkvist 1929). Hamilton (1921-22) and others suggest, however, that salivation is seldom found, at least among hatters with chronic mercurialism. Tylecote (1912) held that the most obvious signs of mercury poisoning were to be found in the mouth, but recently more emphasis has been put on the characteristic tremor.

Tremor.—This is of a coarse intention type, the whole of one or both hands or arms, and se involving the lips, tongue, eyelids, lower lim muscles elsewhere. In severe cases it may af gait, speech, and handwriting. It is easily dis able from the fine tremor of thyrotoxicosis characteristic movements of parkinsonism.

Erethism.—The third principal manifestation psychological disturbance known as erethism. (1929) attributes the first use of this term to John P of London (1758–1826). In this condition the becomes diffident, timid, and easily embarrassed blushes easily; he may become short-tempered and to being watched. More serious mental distu used to be seen in severe chronic mercury intox

Albuminuria has been mentioned by some but denied by others. A specific blood [illegible] thought by some to occur, but Brigatti and Bald deny that there is a specific anæmia attrib mercury poisoning.

CLINICAL INVESTIGATION

When the possibility of mercurialism arising fingerprint work in the Lancashire Constabulary recognised, the officer in charge of the men and 31 the 32 members of his staff volunteered for Mercury excretions were determined by analysing 2 specimens of urine.

A record had been kept of the *number* of investigated by each man *in the past* few year since the developing of latent fingerprints tak average 1–1½ hours per crime, some estimate degree of exposure can be attempted. In practice must vary greatly with the circumstances of each Each man kept an accurate record of his exposure the fortnight preceding the examination.

Of the 32 men, 7 exhibited tremor, with or w other evidence of mercurialism. This tremor, was coarse and distinctive though usually not severe, affected the hands in every case. In 3 ca affected also the lips and tongue, *and in* 3 the ey One man had so severe a tremor that he could n a full cup to his lips without spilling it. His hist as follows:

A detective sergeant, aged 45, had joined the police age of 21 and spent the first eleven years of his serv foot-patrol duties. In 1936 he was trained at the fing department, and, after a few months, he was sent to division where he had to investigate *about* 300 crimes for three years. During this time he became "a wreck" and gave up smoking to try to cure himself, w success. He was then *unable to hold* a glass of water wi spilling it, and even his ten-year-old child remarked o tremor. Before long he found that giving evidence in was "becoming *a nightmare*"; he could not stand answer questions without embarrassment.

During the early years of the war crime diminished division, and his *symptoms seemed to become* less pronou In 1946 *and* 1947 they became worse *again,* reflecting a descence of breaking-in offences, but they were *not* so ba in 1936–39. Of late his exposure *and* his symptoms lessened, because more men *had been able to* help him various times his gums had been very tender, but they s bled. He did not complain of excessive salivation.

On examination five of his teeth were loose, and present in his hands, tongue, eyelids, and rectus abdom muscles. The tremor was coarse and irregular, being of in tion type. His *speech* sounded tremulous and som halting. His gait was normal, but his handwriting was sl irregular compared with a specimen of *seventeen* years be and writing required *great* concentration. His mental appeared *normal*. The tendon-reflexes were brisk.

The history of this case is remarkable in that severity of the man's symptoms had a direct relation to the intensity of his exposure, even *though* at interview he did not attribute the symptoms to his

tremor had been at its worst he had been te drinker of beer, but now he took less and r for it. His embarrassment in the courts indicates mercurial erethism, and the periodic s of the gums can also be considered a specific

the other 6 positive cases there was evidence r present erethism. One constable volunteered was "getting hypersensitive," had profuse at the slightest mental stress, blushed easily, becoming short-tempered with children; he erately severe tremor of hands and eyelids. lushed easily, was embarrassed when questioned, remor of hands, lips, and tongue. In the other symptoms and signs were milder, but could ess be attributed to mercurialism. All the nen drank beer from time to time.

aminations revealed no evidence of bleeding stomatitis. One man with tremor had loose d others too had noted loosening of teeth from me. In one case every tooth in the man's mouth , but this was not considered sufficient evidence rialism, since he had no tremor or signs of As a group these men were intelligent and istomed to have their teeth attended to.

EXPOSURE TO RISK

affected men had all had protracted exposure owder: 2 had been exposed for thirteen years, lve years, 1 for seven, 2 for five, and 1 for four n the last 3 cases the exposures were 250, 250, hours per year regularly. In the remainder s had been more variable but had often reached . Thus in the preceding year, for which accurate s were available, one man was exposed for 160 t all the rest were exposed for 250–460 hours. trast there was another group of men each with iated exposure of less than 100 hours a year. these were employed searching the files at head- , but they were also on a roster to investigate nes of crime. None of them showed any sign of lism.

Eleven men had recently been exposed to risk at the average rate of 250 hours or more per year. It is significant that this group included all the 7 men with mercurialism, and of the other 4, 1 had been at work like this for only eight months. Two men were exposed regularly for $3^1/_2$–4 hours a day while powdering and photographing small articles in the headquarters photographic room. In spite, therefore, of exposures of some 1000 hours per year, neither man was affected. The amount of time they spent in powdering was small; their work appeared to be more circumscribed, and they may have been applying powder less liberally than did their colleagues elsewhere in the county.

URINARY MERCURY ESTIMATIONS

Twenty-four hour specimens of urine collected with scrupulous attention to cleanliness were estimated by a modification of the dithizone extraction technique (Milton and Hoskins 1947). The excretion of mercury varied widely from case to case, lying between 15 and 456 µg. per 24 hours, with a mean of 84·5 µg. In a group of 14 normal persons previously investigated (Buckell et al. 1946) the mean was 31·5 µg., with limits of 5–90 µg. The accompanying table shows that excretions in the present group bear no apparent relation to the declared exposures to risk measured as hours of work, whether recent (in the fortnight before the investigation) or more remote (in the preceding year).

Five of the men with clinical mercurialism had excretions below the general average; the most obvious case of all had a low excretion. The 2 men whose excretions were highest were normal on examination. It is true that they had both been at risk intermittently for twelve years or more, but 2 others exposed for the same time had low excretions.

Note was taken of the amalgam fillings in the teeth of these men, but no relation could be demonstrated between the number of fillings and the excretion of mercury. None of the teeth had been filled recently. Storlazzi and Elkins (1941) found that the mercury in urine almost disappeared by a week after dental fillings had been done. None of the urine specimens contained albumin.

DISCUSSION

The abnormalities discovered among this group of policemen must be attributed to chronic mercury poisoning. Thus an occupational disease of great antiquity appears in a new form, for we can find no published reference to a similar outbreak. Fortunately most of the cases were mild. If there was a danger of chronic mercurialism in the developing of latent fingerprints by this method, it is reasonable that evidence of abnormality should have appeared, as it has done, in members of this particular bureau, for it is unlikely that exposure like this would be encountered in many other police forces in Great Britain. Nevertheless, from time to time a great many men engaged on such duty must be at risk to a lesser degree, and the possibility of unusual individual susceptibility, so often met with in toxicology, must not be overlooked.

The officer in charge of the bureau told us of incidents which suggested that earlier cases may have gone unnoticed. In particular, there had been a colleague of somewhat eccentric habits who could not tolerate being watched at work. This was remarked on long before the possibility of mercurialism had been suggested. In retrospect the story of this man unmistakably suggested erethism.

It is difficult accurately to define these exposures to mercury-with-chalk powder. But, when careful estimates are made in terms of average number of hours per year, it seems that exposures of 250 hours or more constitute a real risk. In one case the recent exposure had been much below this figure.

In individual cases the amount of mercury excreted in the urine is clearly not a reliable guide either to the degree of exposure or to the presence of overt mercurialism. This is agreed by other workers (Neal et al. 1941, Smith and Moskowitz 1948). Nevertheless, the average excretion of members of this group was nearly three times the normal average, and 9 men had excretions above the highest figure in the control series cited above. The high average figure for the group at least bears out the clinical finding of mercurialism among some of its members.

The route of absorption is probably by inhalation of fine dust, but it is possible that some mercury vapour can be inhaled from the powder left lying about. The men's hands are covered in powder while they are working, and direct absorption through the skin or transference of powder by mistake to the mouth might also occur. The men all try to wash after working with powder but cannot always do so.

PREVENTION

Masks and gloves are not a practical solution to this problem. It seems best that the use of grey powder for developing latent fingerprints should be abandoned, provided that a good substitute can be found. At the time of this investigation Detective Chief Inspector Campbell, the officer in charge, was already experimenting to find an even more efficient powder than mercury-with-chalk. He has evolved one which is technically an improvement, since it will fluoresce more brightly in ultraviolet rays, and contains no mercury. The Chief Constable decided to make a change forthwith, and, from the day after this investigation, forbade the use of grey powder throughout the area. It is suggested that other police forces should follow this example.

SUMMARY

The standard method of developing latent fingerprints with mercury-with-chalk powder is described.

Out of 32 men engaged regularly on such work, 7 were found to have evidence of chronic mercurialism.

This appears to be a new form of a long-established occupational hazard.

Exposures in excess of 250 hours per year are considered to constitute a definite risk.

Urinary mercury estimations were of no assistance in diagnosing individual cases or estimating exposures, but the average excretion of the group was abnormally high.

We are most grateful to Sir Archibald Hordern, C.B.E., Chief Constable of Lancashire, for permission to conduct the examinations, for his lively interest, and for the prompt action which was taken when the hazard was shown to exist. On the suggestion of Mr. J. N. Aldington, PH.D., of Preston, Detective Chief Inspector Campbell, of the Lancashire Constabulary, brought this matter to our attention, and we wish to thank him for his kindness, enthusiasm, and invaluable help, and members of his staff for their cooperation. We wish to thank Dr. Donald Hunter, Director of the Department, for his help and encouragement, and Miss S. Pratt and Miss G. de Gabriele for technical assistance.

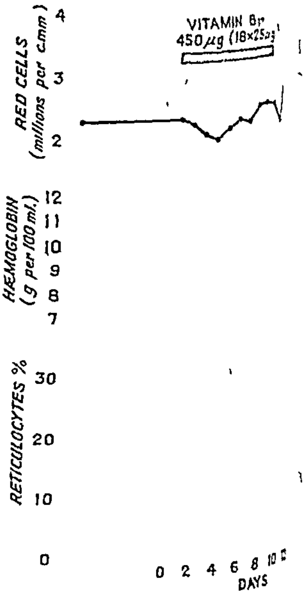
IN the last few years great progress has in the understanding of chemical compounds promote blood regeneration in pernicious Three distinct chemical substances have been shown to be effective—folic acid or ptero acid (Spies 1947); thymine or 5-methyl ura et al. 1946); and vitamin B_{12} (West 1948, S 1948). The chemical structures of folic thymine are known, but the complete st vitamin B_{12} is still unknown. Vitamin B_{12}, adequate amounts, protects the nervous system of persons with pernicious anæmia, which neither folic acid nor thymine does. The excessive amount of thymine required—about 15 g. daily—makes it impractical as a therapeutic agent, and it will not be discussed further here. Folic acid, though not a complete treatment for pernicious anæmia, is especially useful in nutritional macrocytic anæmia and sprue.

Recently vitamin B_{12} has been isolated from liver extract (Rickes et al. 1948a) and from streptomycin residues (Rickes et al. 1948b) and has been show



Hæmopoietic response of case 1 (macrocytic anæmia) to vitamin B mouth. A similar response, in relapse in this case, followed intramuscular injection of 75 µg of B_{12}. This was the most dramatic seen in this study.

cyte peak (6th day treatment)	—	—	21·0
days after treatment	2·82	8·2	0·6

Case 3.—A woman aged 77. Hæmopoietic response to one dose of vitamin B_{12} 100 µg. by mouth:

	Red cells	*Hb*	*Reticulocytes*
Initial	2·70	11·0	0·8
Reticulocyte peak (6th day after treatment)	—	—	2·6
Ten days after treatment	2·81	10·4	0·4

Second Study after 2 Weeks' Interval

Hæmopoietic response to one dose of vitamin B_{12} 400 µg. by mouth:

	Red cells	*Hb*	*Reticulocytes*
Initial	2·70	11·3	1·0
Reticulocyte peak (4th day after treatment)	—	—	2·0
Ten days after treatment	2·81	10·9	0·2

Third Study after 2 Weeks' Interval

Hæmopoietic response to one intramuscular injection of vitamin B_{12} 45 µg.:

	Red cells	*Hb*	*Reticulocytes*
Initial	2·64	12·0	0·6
Reticulocyte peak (4th day after treatment)	—	—	2·4
Twelve days after treatment	3·02	11·3	0·4

NUTRITIONAL MACROCYTIC ANÆMIA (17 CASES)

Case 4.—A man aged 68. Hæmopoietic response to vitamin B_{12}, 150 µg. by mouth daily for twenty days:

	Red cells	*Hb*	*Reticulocytes*
Initial	2·54	9·1	4·3
Reticulocyte peak (9th day of treatment)	—	—	25·1
Twentieth day of treatment	3·55	12·1	8·4

Case 5.—A woman aged 56. Hæmopoietic response to one dose of vitamin B_{12} 500 µg. by mouth:

	Red cells	*Hb*	*Reticulocytes*
Initial	2·40	9·3	1·0
Reticulocyte peak (7th day after treatment)	—	—	10·9
Twelve days after treatment	3·03	10·1	2·4

Second Study after 6 Weeks' Interval

Hæmopoietic response to vitamin B_{12} 150 µg. daily by mouth for twenty-seven days:

	Red cells	*Hb*	*Reticulocytes*
Initial	2·37	8·6	2·4
Reticulocyte peak (11th day of treatment)	—	—	13·3
Twenty-seventh day of treatment	3·47	11·1	3·2

TROPICAL SPRUE (14 CASES)

Case 6.—A man aged 69. Hæmopoietic response to one dose of vitamin B_{12} 500 µg. by mouth:

	Red cells	*Hb*	*Reticulocytes*
Initial	1·50	8·6	0·2
Reticulocyte peak (9th day after treatment)	—	—	9·0
Ten days after treatment	1·83	10·0	0·8

Second Study after 3 Weeks' Interval

Hæmopoietic response to vitamin B_{12} 150 µg. by mouth daily for forty-five days:

	Red cells	*Hb*	*Reticulocytes*
Initial	1·53	9·4	0·8
Reticulocyte peak (13th and 19th days of treatment)	—	—	7·0
Forty-fifth day of treatment	2·38	11·4	0·1

Case 7.—A man aged 62. Hæmopoietic response to one dose of vitamin B_{12} 30 µg. by mouth:

	Red cells	*Hb*	*Reticulocytes*
Initial	1·29	2·7	1·4
Reticulocyte peak (9th day after treatment)	—	—	3·4
Twelve days after treatment	1·30	6·2	0·2

Second Study after 3 Weeks' Interval

Hæmopoietic response to one dose of vitamin B_{12} 500 µg. by mouth:

	Red cells	*Hb*	*Reticulocytes*
Initial	1·81	8·7	0·4
Reticulocyte peak	—	—	None
Ten days after treatment	2·30	8·8	0·1

Third Study after 6 Weeks' Interval

Hæmopoietic response to one dose of vitamin B_{12} 1500 µg. by mouth:

	Red cells	*Hb*	*Reticulocytes*
Initial	1·19	4·8	0·8
Reticulocyte peak (8th day after treatment)	—	—	9·0
Twenty-one days after treatment	1·86	7·1	0·4

Case 8.—A man aged 72. Hæmopoietic response to one dose of vitamin B_{12} 30 μg. by mouth:

	Red cells	Hb	Reticulocytes
Initial	2·45	10·4	0·2
Reticulocyte peak	—	—	None
Ten days after treatment	2·55	10·1	0·2

Second Study after 4 Weeks' Interval

Hæmopoietic response to one dose of vitamin B_{12} 300 μg. by mouth:

	Red cells	Hb	Reticulocytes
Initial	1·92	8·4	0·2
Reticulocyte peak (6th day after treatment)	—	—	3·2
Ten days after treatment	1·94	8·0	0·2

Third Study after 2 Weeks' Interval

Hæmopoietic response to vitamin B_{12} 150 μg. daily by mouth for twenty days:

	Red cells	Hb	Reticulocytes
Initial	1·71	7·3	0·2
Reticulocyte peak (8th day of treatment)	—	—	2·2
Twentieth day of treatment	1·58	6·9	0·4

Fourth Study after 2 Weeks' Interval

Hæmopoietic response to intramuscular vitamin B_{12} 30 μg. daily for three days:

	Red cells	Hb	Reticulocytes
Initial	1·47	7·8	0·4
Reticulocyte peak (7th day after treatment)	—	—	20·1
Eleven days after treatment	2·78	9·4	0·2

We are making special studies on this man. He does not seem to absorb any substance effectively from his alimentary tract.

NON-TROPICAL SPRUE (2 CASES)

Case 9.—A man aged 64. Hæmopoietic response to one dose of vitamin B_{12} 50 μg. by mouth:

	Red cells	Hb	Reticulocytes
Initial	2·36	6·6	1·0
Reticulocyte peak (3rd day after treatment)	—	—	3·0
Four days after treatment	1·73	6·3	3·3

Second Study after a Week's Interval

Hæmopoietic response to vitamin B_{12} 450 μg. by mouth daily for six days:

	Red Cells	Hb	Reticulocytes
Initial	1·73	7·1	2·0
Reticulocyte peak (4th day of treatment)	—	—	9·1
Fourteen days after treatment	2·32	8·6	2·7

CONCLUSIONS

The minimum, maximum, and optimum dose of vitamin B_{12} varies from patient to patient and from time to time in the same patient; therefore no routine of treatment can be followed satisfactorily. The best method will have to be found for each case. As soon as possible, the patient should have a diet that supplies adequate calories and a liberal amount of protein of high biological value.

Vitamin B_{12} is more efficacious per unit of weight when given parenterally than when given by mouth, as is shown in cases 2 and 7. Irrespective of age or any other condition, vitamin B_{12} should always be given parenterally when the patient has severe cardiac failure, severe neural degeneration, or a severe alimentary disturbance. In most extremely ill patients the initial treatment at least should be parenteral. Nevertheless this report shows that vitamin B_{12} given by mouth in adequate amounts is often efficacious. It must be recognised, however, that some patients have macrocytic anæmia with megaloblastic arrest of the bone-marrow which does not respond to liver extract, folic acid, or vitamin B_{12}, whether given parenterally or by mouth. There were several such patients in the present series. On the whole, most patients respond slowly when vitamin B_{12} is given by mouth in an amount 30–60 times by weight that required for parenteral therapy.

Parenteral administration produces more rapid improvement, ensures that altered gastro-intestinal function cannot block absorption, and can always be supervised by a physician, thus eliminating the bility of interference where the patient has an aversion to injections. Moreover, though we seen a patient who is allergic to vitamin B_{12} or the concentrates of it, almost certainly such a pa eventually be found. Some patients acquire a to parenteral liver extract so that injections reactions varying in intensity from mild to In such cases oral administration is often e vitamin B_{12} by mouth may be useful where a reacts severely to injections of the substance.

This study was aided by a grant from the National Foundation, Inc. The vitamin B_{12} was supplied Augustus Gibson, of Merck & Co., Inc., Mr. W. R. and Dr. H. Sidney Newcomer, of E. R. Squibb & Dr. E. Gifford Upjohn and Dr. Earl L. Burbidge, of the Company.

LONDON HOSPITAL

THE increased availability of radioactive i recently led to its use in the assessment of function in man. Methods have been desc determining the uptake of iodine by the th disappearance from the blood, and its excretion in Most investigators have administered radioactive by mouth, and it has been shown that, in ge least 98% of the tracer dose will be rapidly absor the blood-stream (Hamilton and Soley 1939), justifies the assumption that all the dose is a and determinations of activity can therefore be e as a percentage of the dose administered. Altera thyroid function is accompanied by changes uptake of iodine by the gland and in urinary ex The proportion of a dose of radioactive iodine e in the urine has been shown to vary inversely thyroid activity, and this has been used as a di test in thyroid dysfunction. Bulk samples of collected over 24 or 48 hours are sufficient to difference in the percentage of a tracer iodine excreted by normal and thyrotoxic subjects (Mc et al. 1948). Marinelli et al. (1948) noted tha difference is best shown by measuring the excre radio-iodine from the 6th to the 24th hour after a tration of a tracer dose. Keating et al. (1947), intensive study of these curves, developed a met calculation to provide an index of iodine uptake thyroid.

The present investigation has been undertak determine whether the urinary excretion of radio can be developed as a routine diagnostic test in pa with thyroid disease. It was realised that direct tion of thyroid uptake, in conjunction with estin of blood-iodine (Myant et al. 1949), gives a more picture of thyroid function than do urinary values for routine use a method must be simple and inva he patient. Radioactivity in urine can be d accurately with very low doses of tracer urther, the method involves less apparatus and space than does direct thyroid counting and y disturbance of the patient. To determine nethod of using the urinary excretion of radio- an index of thyroid activity. Keating's method ting thyroid uptake was compared with excre- ies measured on bulked samples of urine. ictors, other than thyroid activity, which might excretion of radio-iodine were also investigated.

METHOD

ome preliminary trials a standard dose of about uries of I^{131}, measured according to the Medical Council (1948), was adopted. This was found urinary excretion suitable for measurement in of thyrotoxicosis: in people with normal or ed thyroid function the dose can be reduced to uries. The irradiation of the thyroid by a curie dose can be calculated from the figures Marinelli et al. (1948). If all the dose is taken thyroid weighing 25 g. and evenly distributed ut the gland, the thyroid will receive about 5 r st day and a total of about 60 r in three weeks. not all the dose will be taken up by the thyroid, etion from the gland will further reduce the received. In a normal person there may be 50% collection by the thyroid and a dose of uries will have a "biological" half-life in the of about six days instead of the physical half-life days: in this case the thyroid radiation will be r in the first day, with a total of about 12 r. to other parts of the body will be at a very wer level. The radiation hazard with such a s considered to be negligible.

ndling of I^{131} was carried out with precautions o those outlined by the Ministry of Supply (1949). isite dose of I^{131} (carrier-free as supplied) was mixed ml. of distilled water to which about 50 µg. of inert odide had been added. A mixture of radioactive ith inert carrier iodide is always advisable to reduce e tracer material by adsorption on to glassware &c., small amount of carrier iodide is not sufficient to roid activity. As a standard solution for comparison ctivity with the urine samples, 5 ml. of the prepared s added to 45 ml. of sodium iodide solution (1%). aining 45 ml. of the dose was drunk by the patient; ter was rinsed with distilled water, and this was also ered. The dose was usually given about 2 hours eakfast, and complete urine collections were made 9, 12, and 24 hours later. Inert sodium iodide (10 ml.) was added to each sample of urine directly een passed.

volume of each urine sample was recorded, and ivity was measured on a 10 ml. sample. The agree- duplicate samples was very satisfactory. A glass ounter of the type described by Veall (1948) was conjunction with conventional quenching and scaling The total activity of each sample was compared e standard solution and was expressed as a percentage ose administered.

inimise contamination errors in the counter, the were counted in order of increasing activity, beginning e last specimen passed and ending with the standard. ach measurement the counter was carefully rinsed ert iodide solution, and a background count was d. With this technique the background count was ined at a reasonable level.

vance must be made for the "dead time" of the with high rates of counting. In practice this correc- as negligible, since count-rates were below 3000 per If necessary the standard was diluted to give the rder of count-rate. For convenience, counting-time ept short, an accuracy of about 5% being found nt. An accuracy of up to 1% can be obtained by ing the counting-time when only one or two samples be counted, but after longer counting-times decon- ation of the counter is more difficult.

RESULTS

A comparison of the 24-hour excretion of I^{131} in urine was made in 54 patients in whom the clinical evidence clearly indicated normal, increased, or decreased thyroid activity. Excretion studies were also made on 16 patients in whom the clinical diagnosis of thyrotoxicosis was doubtful. In 9 patients excretion tests were repeated, and the results were reproducible within the variation seen from case to case in the normal people.

A total of 28 excretion tests was performed on 16 normal subjects convalescing from some unrelated disorder; these included 12 men and 13 women, aged 14–60 years, free from any evidence of intestinal, thyroid, or kidney disorder. Seven cases of myxœdema were studied, 3 with well-marked clinical features of the disease. There were 22 patients with undoubted evidence of increased thyroid activity; these included 4 males and 18 females aged 16–67. On the clinical assessment, including the basal metabolic rate (B.M.R.), thyrotoxicosis was severe in 7, moderate in 11, and mild in 4.

The 24-hour excretion of radio-iodine varied from 5 to 26% of the administered dose in thyrotoxicosis, and from 28 to 72% in normal people (fig. 1). This gave a reasonable difference between the means for the two groups, but there was a wide scatter in the normal series. The values in myxœdema were within the normal range.

A more satisfactory separation was obtained by subdividing the 24 hours of observation. In the first 6 hours after administration of I^{131} the percentage excreted was not much different in normal people and in thyrotoxic patients; but the subsequent period of excretion, from 6 to 24 hours, showed a clear separation between the two groups. During this period the amount of I^{131} excreted by normal people varied from 10 to 25%, whereas the highest amount excreted by any thyrotoxic patient was 4·5%, and most of them excreted under 2%. Further, percentage excretion over the 6–24 hour period was more closely related to the clinical assessment than was 24-hour excretion. The difference between the normal person and the hypothyroid patient was not so well marked; thus over this period the myxœdematous patients gave a percentage excretion varying from 26 to 39%.

In the whole series it was found that a 6–24 hour excretion of under 4% of the tracer dose indicated definite thyroid overactivity. Excretion of over 25% was characteristic of myxœdema.

Our figures for radio-iodine excretion were analysed in an attempt to confirm Keating's findings and to compare the results of his more elaborate method of calculation with the examination of bulk samples described above. In general it was found that the summed urinary excretion plotted against time approximated to an exponential form, and a mean exponential curve could be drawn through the actual values. Any gross variation of one sample from this mean curve was always found to result from an error in urine collection: so inspection of the curve provided a useful check on the accuracy of the collections. Typical curves obtained for the three groups of patients are shown in fig. 2.

There are, however, variations from exponential form towards the end of the excretion period. In normal persons and in myxœdematous and "doubtful thyrotoxic" patients a mean exponential can be drawn to include all individual urine samples throughout 24 hours, but in undoubted thyrotoxicosis the excretion is of exponential form only in the earlier stages, after which follows a period of roughly linear excretion. In general the greater the degree of thyrotoxicosis the more quickly does the exponential phase of excretion cease. Keating et al. (1947) concluded that the amount of excretion after the exponential phase was related to the degree of thyrotoxicosis, but our results do not bear this out.

The rate of thyroid uptake of iodine was next calculated by Keating's method (see appendix). In this calculation it is assumed that the total tracer dose is absorbed very quickly into the blood-stream, and that the removal from the blood only takes place via the kidney and the thyroid. Renal excretion follows an exponential form and it is assumed that the thyroid uptake follows a similar pattern—i.e., the rate of removal of iodine from the blood-stream by either organ is proportional to the concentration in the blood. Each route of loss will be characterised by its own rate factor, the total rate factor for disappearance from the blood being the sum of renal and thyroid rates. The thyroid-rate factor is an index of the speed of thyroid collection of iodine and should parallel thyroid activity.

The thyroid rates in the groups already described are represented in fig. 1. The normal range was 0·055–0·1 per hour. In myxœdema it varied from 0·005 to 0·04 per hour, the higher values being obtained in the less severe cases. There was a wide range in the thyrotoxic group, from 0·28 to 1·18 per hour, and the greater the clinical severity of the thyrotoxicosis the higher was the thyroid rate. The thyroid rate of the mildest case of thyrotoxicosis was more than double the highest normal rate. The mean normal value was about 0·08. In this series myxœdema always gave less than half, and thyrotoxicosis more than three times, the mean normal value. In severe hyperthyroidism the rate was above five times the mean normal.

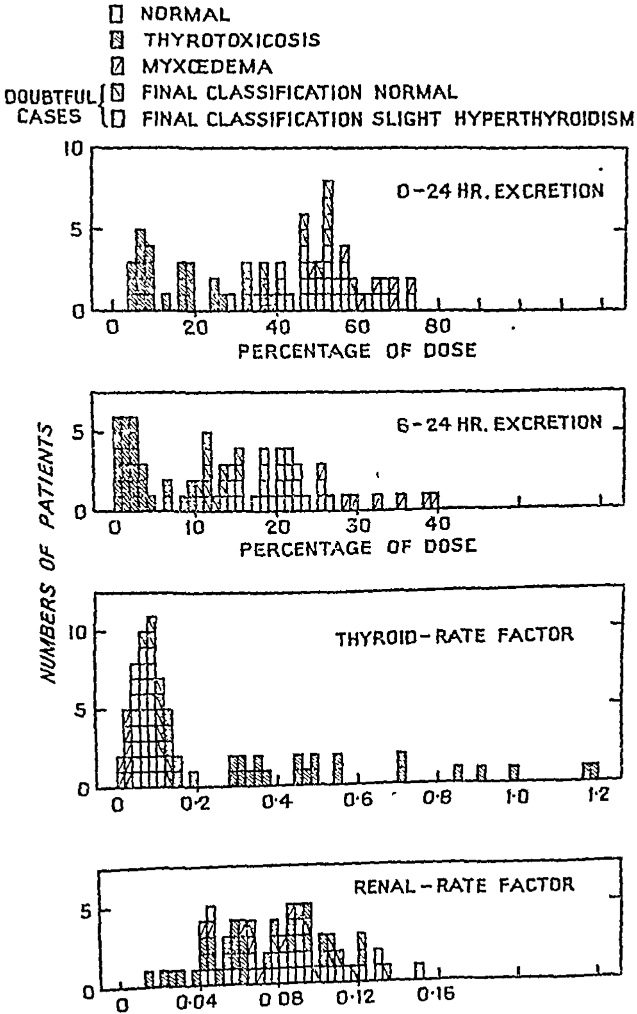

Fig. 1—Urinary excretion of radio-iodine by normal people and in thyrotoxicosis and myxœdema.

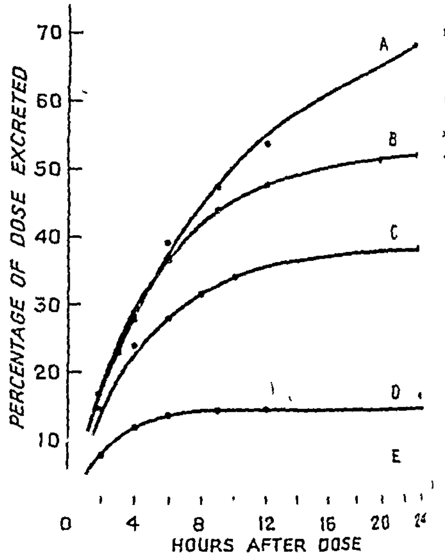

Fig. 2—Urinary excretion of radio-iodine in different stat œdema; B, normal health; C, slight hyperthyroidism; D thyrotoxicosis; E, severe thyrotoxicosis.

Doubtful Cases of Thyrotoxicosis

Excretion tests were performed in 16 pa whom the diagnosis of hyperthyroidism was d The presenting symptoms included nervousne cardia, sweating, loss of weight, and, in some enlarged thyroid. The change in B.M.R. in the was of doubtful significance. Radio-iodine (fig. 1) fell within the normal limits in 10 ca between the normal and hyperthyroid excretion in 6. Clinical assessment based on observation in and on subsequent progress showed a close with the excretion results. Thus, in the case within the normal range the symptoms app more directly attributable to an anxiety sta responded satisfactorily to non-specific the 6 cases outside the normal range the clinical ment favoured mild hyperthyroidism in 5; all, have improved without specific anti-thyroid

The results of radio-iodine excretion tests important group indicate that no sharp line drawn between normal and increased thyroid but they do appear to provide a means of d nating between symptoms attributable to an state and the very similar symptoms associated hyperthyroidism.

POSSIBLE SOURCES OF ERROR

Radioactive iodine was administered to a n patients to investigate the possibility of errors from renal failure, previously administered iodine, sweating, generalised anasarca, defective ab-o and biliary excretion of iodine. The following were obtained.

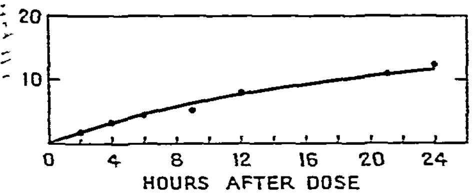
A recognised source of error in assessing function by measuring excretion of radio-iodine impairment of renal function. Four cases of Bright's disease with renal failure (impaired concen power and nitrogen retention) were investigated, all only a small proportion of the dose was excr 24 hours (fig. 3). The excretion figures were 12 18·9, and 26%, which give a false impression of overactivity. This impression was partially c by the 6–24 hour excretion of 7·6, 8·7, 12, and The curves of radio-iodine excretion could be inte on an exponential basis in 3 of the 4 patients, were about 0·01 per hour, or well below the ɡe. The thyroid rates were around the lower rmal, showing that this method of analysis onable correction for considerable alterations ction.

ıerapy before administration of radio-iodine se the excretion of radio-iodine and may normal excretion curve in a patient with yrotoxicosis. The following case illustrates

dide was administered for 3 weeks in a moderately of hyperthyroidism. The radio-iodine excretion then within normal limits, with a 6–24 hour 29·3% and thyroid rate of 0·04 per hour, though f thyrotoxicosis were still manifest.

of the excessive sweating often associated otoxicosis it was decided to measure the ı of I^{131} in the sweat. One normal person ous exercise for 2 hours, and another for fter a dose of I^{131}, and sweat was collected ag one arm in a Stallard-Bunyan bag; 10 ml. of sweat from these peoples contained only ıd 0 012% of the ingested dose. It was not , therefore, that loss of tracer iodine in the ld introduce a significant error in determining ınction. Excretion of I^{131} was also measured le of two patients whose common bile-ducts g drained surgically. The I^{131} content of a ollection of bile was 0·5% and 0·6% of the inistered.

w cases the early excretion values were low appeared to be a delay before the excretion ame exponential in form. This was found in



inary excretion of radio-iodine by patient with renal failure.

rmal people (fig. 4, curve A), and a more pro- delay was shown in two tests in a severe case orrhœa (fig. 4, curve B). This effect may be d with slow absorption from the gut. If all the finally absorbed, neither the total urinary n nor the calculated thyroid rate will be affected. ever, a part of the dose is not absorbed, a false re will be obtained for urinary excretion which l to a false high value for the calculated thyroid he rate factor for the disappearance of I^{131} from od will, however, be unaffected. Though some s detected in the fæces of the patient with hœa, no disparity was found between the thyroid- ctor and the 24-hour excretion either in this or in the normal people with delayed excretion. ncluded that such loss as may occur with absorp- fects is unlikely to introduce significant error in erpretation of urinary radio-iodine excretion.

ated tests in a patient with and without fever no significant difference between the two results. se of constrictive pericarditis, with serous effusions ome generalised œdema, radio-iodine excretion ormal in all respects, and was not significantly when a second tracer dose was given immediately he removal of 4 pints of pleural fluid and an on of 'Neptal' which doubled the urinary output. onal factors did not appear to alter the excretion n any way.

DISCUSSION OF RESULTS

The 0–24 hour excretion, 6–24 hour excretion, and thyroid-rate values in normal people and patients with thyroid disorder are compared in fig. 1. A close correlation is found between the 6–24 hour excretion and thyroid rates for all groups of patients. The normal range of 20–10% in 6–24 hour excretions corresponds to a range of 0 06–0·12 in the thyroid rate. The 6–24 hour excretion is as reliable as the calculated thyroid rate merely as an aid to the diagnosis of thyrotoxicosis and it is more simple for routine use. In severe and moderately severe cases of thyrotoxicosis, however, the thyroid-rate values give a wider scatter (0·48 to 1·18) than the 6–24 hour excretion, since the latter falls below 2·5% in these cases. For this reason the thyroid rate gives a more accurate quantitative indication of thyrotoxicosis.

In distinguishing between normal people and patients with myxœdema both methods gave some assistance, but neither is really satisfactory, and it is felt that further work covering the 24–48 hour excretion period is necessary.

It must be remembered that the clinical picture of thyrotoxicosis is not absolutely related to the degree of thyroid activity, since individual sensitivity to thyroid hormone may vary and other factors contribute to the clinical picture. Thus, in a thyrotoxic patient the pattern of radio-iodine excretion indicates the degree of thyroid activity and not necessarily the clinical state.

SUMMARY AND CONCLUSIONS

The estimation of urinary excretion of radioactive iodine, I^{131}, administered by mouth is a valuable diagnostic aid in thyroid disease. The method can be made simple and safe enough to justify its use as a routine procedure. A dose of 10 microcuries has been found sufficient and is recommended as a maximum for this investigation.

Measurement of excretion in bulked urine samples collected between the 6th and 24th hour after administration of the dose provides a reliable diagnostic test for thyrotoxicosis. In the present series a 6–24 hour excretion of under 4% indicated definite thyroid overactivity, excretion of 10–25% occurred in normal people, and over 25% was typical of myxœdema.

Plotting of the urinary excretion curve and derivation of the thyroid-rate factor as suggested by Keating et al. (1947) gives a more satisfactory separation of the thyrotoxic from normal persons and provides a better estimate of the degree of overactivity than does measurement of a bulked sample. The results in myxœdema

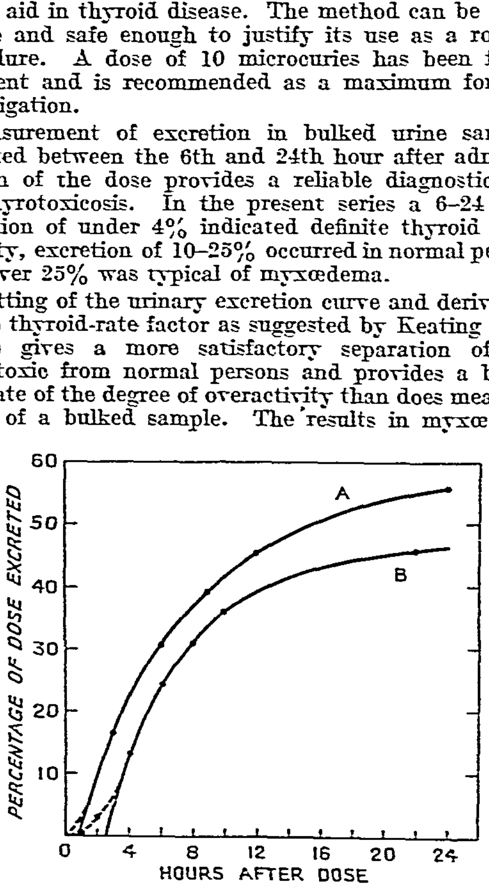


Fig. 4—Delay in exponential form of curve of urinary excretion of radio-iodine by: A, normal person; B, patient with steatorrhœa.

are of diagnostic value but are less clear-cut. In the present series the range of the calculated thyroid rate was 0·005–0·04 per hour in myxœdema, 0·055–0·12 per hour in normal people, and 0·28–1·18 per hour in thyrotoxicosis.

The method provides a satisfactory diagnostic aid in cases of doubtful thyrotoxicosis.

Loss of radio-iodine in sweat and bile is unlikely to be greater than 2–3% of the dose and will not appreciably affect estimates of thyroid activity. Impairment of renal function makes interpretation of the excretion curve difficult and may invalidate the result.

We wish to acknowledge the encouragement and interest of Prof. Clifford Wilson and Mr. Frank Ellis, and the help of Mr. W. S. Hartnell, who has assisted in the radioactive assay.

APPENDIX

Adopting Keating's terminology, if Q_f is the proportion of the dose finally excreted by the kidney, and r is the rate factor for disappearance of iodine from the blood, then the renal-rate factor is given by Q_f, and the thyroid-rate factor by $r(1-Q_f)$. It is possible to derive the values of r and Q_f, and therefore of the thyroid-rate factor $r(1-Q_f)$, directly from the curve of urinary excretion. Thus the value of the thyroid-rate factor is obtained independent of renal function.

The method of analysis given by Keating may be expressed mathematically as follows:

If Q_B is the proportion of the tracer dose in the blood after a time t, then:

$$\begin{aligned} \text{rate of loss from the blood into the thyroid} &= r_tQ_B \\ \text{,, ,, ,, ,, ,, ,, ,, ,, kidney} &= r_uQ_B \\ \text{and total ,, ,, ,, ,, ,, ,,} &= -\frac{dQ_B}{dt} = (r_t+r_u)Q_B \\ &= rQ_B \\ \text{and } Q_B &= e^{-rt} \end{aligned}$$

where r is the rate factor for disappearance from the blood, and r_t and r_u are the thyroid-rate and renal-rate factors respectively. The rate of appearance of labelled iodine in the urine

$$=\frac{dQ_u}{dt} = +\,r_uQ_B = +\,r_ue^{-rt}$$

Integrating this gives

$$Q_u = -\left(\frac{r_u}{r}e^{-rt}\right) + A \quad . \quad . \quad . \quad (1)$$

where A is the integration constant.

For $t = 0$, $Q_u = 0$, so $A = +\frac{r_u}{r}$

For $t = \infty$, Q_u = the proportion of the dose which is finally excreted $= Q_f$.

So $A = Q_f$, and $r_u = rQ_f$.

Therefore $r_u = rQ_f$ and $r_t = r(1-Q_f)$ as given in the text.

Equation (1) becomes

$$Q_u = Q_f\,(1-e^{-rt}) \quad . \quad . \quad . \quad (2)$$

This is the equation for the curve of iodine excretion with time. Q_f may be obtained by drawing in the curve and judging its asymptote. Equation (2) may be rewritten:

$$\log_e (Q_f - Q_u) = (\log_e Q_f) - rt.$$

If then the values of $(Q_f - Q_u)$—i.e., the amount still to be excreted in the urine—are obtained from the estimated Q_f and the observed excretions, and the natural logarithms of these values are plotted against time, a straight line graph will be obtained if the excretion curve is of exponential form. The slope of this straight line gives the value of r, the total rate factor. In practice the values of $Q_f - Q_u$ are plotted against time on log-linear graph paper. This involves the use of logs to base 10 and r is given by:

$$r = \frac{\log_{10} Q_f - \log_{10}\frac{Q_f}{10}}{\left(\text{time for } Q_f - Q_u = \frac{Q}{10}\right)\log_{10}e} = \frac{1}{\left(\text{time for } Q_f - Q_u = \frac{Q_f}{10}\right)\times 0{\cdot}434}$$

It may be found that this second plot does not lead to a straight line. However, *it is usually possible to alter the value* of Q_f slightly until the points do lie along a The log plot therefore provides a method of original estimate of Q_f.

It has long been known that thyroid tissue in its great capacity to concentrate iodine, recently has the development of radioac techniques made measurement of this capacity able. Thus, an additional and much needed c of thyroid function should now be available, the thyroid's avidity for iodine proves a valid the gland's functional state. A tracer dose of iodine, small enough to be an insignificant f patient's usual daily intake of iodine, can be a and its fate followed accurately by measuring activity. Normally, about half the dose is co in the thyroid and the residue is almost entirely in the urine; the radioactivity appearing in thyroid or the urine can be measured to index of thyroid function.

In 1939 Hamilton and Soley published the fi observations made with I^{131}, and many obse have used this isotope to assess the avidity of the for iodine. The rise in concentration of I in the gland may be measured directly in vi tracer dose has been given (Hamilton and S 1940, Hamilton et al. 1943, Werner et al. 1 measuring the plasma levels of I^{131} as well accumulation in the thyroid, Pochin (1948) has the thyroid's rate of clearance of I^{131} from the which he finds a more sensitive index of thyroid Either of these procedures is technically d present. Hertz and Roberts (1942) suggested urinary excretion of I^{131} alone might provide clinical index of thyroid function; and this has been examined by Keating et al. (1947), et al. (1948), and Skanse (1948). These work used relatively large doses of I^{131} and various a carrier, and their "normal" groups included with cancer. A standardised method sufficie and valid for routine clinical adoption has not established. McConahey et al. (1949) studied of radio-iodine in the blood and found that no better index of thyroid function than urinary excretion.

We report here some further studie urinary excretion of I^{131} by 30 normal typical thyrotoxic patients, and 3 hyp patients, and suggest a practicable form for a cli The radiation exposure from the small dose g that often used in X-ray diagnosis. Urine 1 for 48 hours in four subdivisions whose measurement facilitates the detection of from the normal range outlined.

METHOD

of Patient

scertained that no thyroid extract, iodides, thio- or anti-thyroid drugs had been given recently. as given by mouth in the early morning after an fast. No solid food was allowed until an hour se had been drunk. During the period of collection t and activities were allowed, sedatives were not nd the patient was encouraged to drink enough to quate samples of urine at the times of collection.

m iodide 10 µg. containing 10 microcuries of diluted to 50 ml. and transferred to the dose ml. of the dose was then pipetted directly into % potassium iodide solution to serve as the standard ubsequent urine estimation. The patient drank directly from the bottle, which was then rinsed 1 water and the washings were also drunk. This was designed to avoid errors due to adsorption on to glassware.

ses the residue in the bottle was estimated; 5% otassium iodide was left in the bottle for 24 hours xchange between adsorbed I^{131} and inactive iodine ution. The total activity of this solution was not 1 0·04% of the dose.

of Urine

as collected for 48 hours after the dose was drunk. rly investigation samples were taken roughly every the first 8 hours, and for the rest of the 48 hours nes desired by the patient. Later in the investigaples were pooled into four collections: 0–8, 8–12, d 24–48 hours.

ales studied urinated directly into the specimen Females used bedpans for the most part, but a atheter was passed in some, and in others urine was rough a specially arranged funnel directly into the bottle.

e patients examined were in hospital when tested. s taken to ensure that the urine collections were and accurately timed. Six collections whose ss was in doubt were excluded.

on of Activity in Urine

oncentration of radioactive iodine in the urine was d directly with that in the standard solution, by f the Geiger-Müller counter described by Veall (1948) nating liquid samples. The activity in each urine was then expressed as a percentage of the dose ered.

lly, when frequent samples were collected in all tests, nple was counted for five minutes, and so the counting ned with the concentration in the sample, the standard om the first 8 hours being about 1·5%, from the 24th out 10%, and from the 48th hour about 30%; but ndard error of the four pooled collections computed ese data would be less than 7%, and that of the total n less than 1·5%. Later, when only the four pooled ons were measured, counting errors did not exceed limits. Finally, when the following concentration re was adopted for weak samples, all counts involved lard error of less than 3%.

of Concentrating I^{131} in Urine Samples

method involves the precipitation of the urinary as silver iodide, which is then redissolved in a much volume of sodium iodide solution. The resulting n is considerably more dense than the standard solution. onsequently a greater proportion of the radiation is ed before reaching the sensitive volume of the counter. ection must therefore be added to the counting-rate ed before it is compared with that of the standard. By using standard quantities of reagents final solutions of constant density are obtained; hence, the correction to be applied is the same for all samples. The method is accurate to 1% but is not reliable when there is albuminuria or after bacterial decomposition of the urine. Delay in processing samples should therefore be avoided.

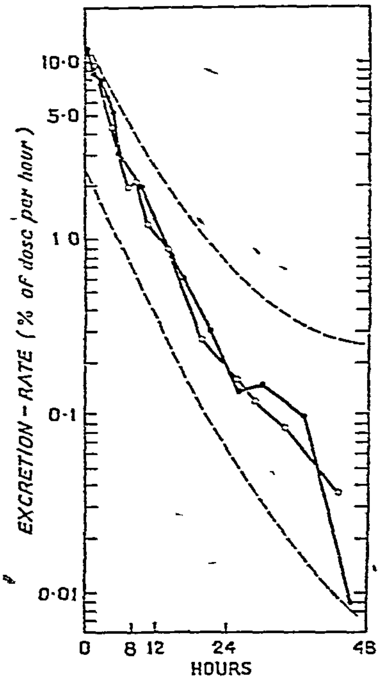

Fig. 1—Results of two tests at 11 months' interval on a normal man. The dose of radioactive iodine (10 microcuries of I^{131} with 10 µg. of potassium iodide) was given by mouth at 0 hours. The curve shows the changing rate of the urinary excretion of I^{131}. Normal observations fall within the area enclosed by interrupted lines (see fig. 2B).

To 5 ml. of a solution of sodium iodide containing 11·8 g. per litre (equivalent to 10 mg. of iodine element per ml.) a measured volume of urine is added, usually 50–200 ml.

Sufficient nitric acid (sp. gr. 1·84) is added to keep the sample permanently acid during the precipitation process which follows; this is indicated by the addition of 1 drop of starch solution.

To the solution 5 ml. of silver nitrate (20 g. per litre) is added drop by drop with constant stirring in the cold. This quantity is sufficient to precipitate all the iodide and a little of the chloride present. The solubilities of silver iodide and silver chloride are such that precipitation of the chloride is delayed until precipitation of the iodide is substantially complete. The blue colour of the starch iodide is, of course, discharged at the end-point.

If the reaction is properly performed with clean (grease-free) utensils, the precipitate should be granular and should settle quantitatively overnight. Centrifuging is often necessary.

When completely settled, the supernatant liquor is removed as far as possible with a finely drawn out tube connected to a water pump. With practice this can be done without loss.

To the sediment is added 5 ml. of sodium iodide solution (472 g. per litre) which is sufficient to dissolve the silver iodide. The solution is then removed with a dropper to a 20 ml. volumetric flask, and the transfer is completed by rinsing with a further 5 ml. of sodium iodide solution introduced in small quantities with the dropper. The flask is

I^{131} was supplied by Oak Ridge National Laboratories through e Medical Research Council. The dose is measured in terms the microcurie adopted by the M.R.C. for 1949. Owing to the ncertainty of absolute measurements of radioactivity there ay be considerable variations between the units used by the arious investigators. This unit equals about 0·7 Oak Ridge icrocuries as supplied in 1948.

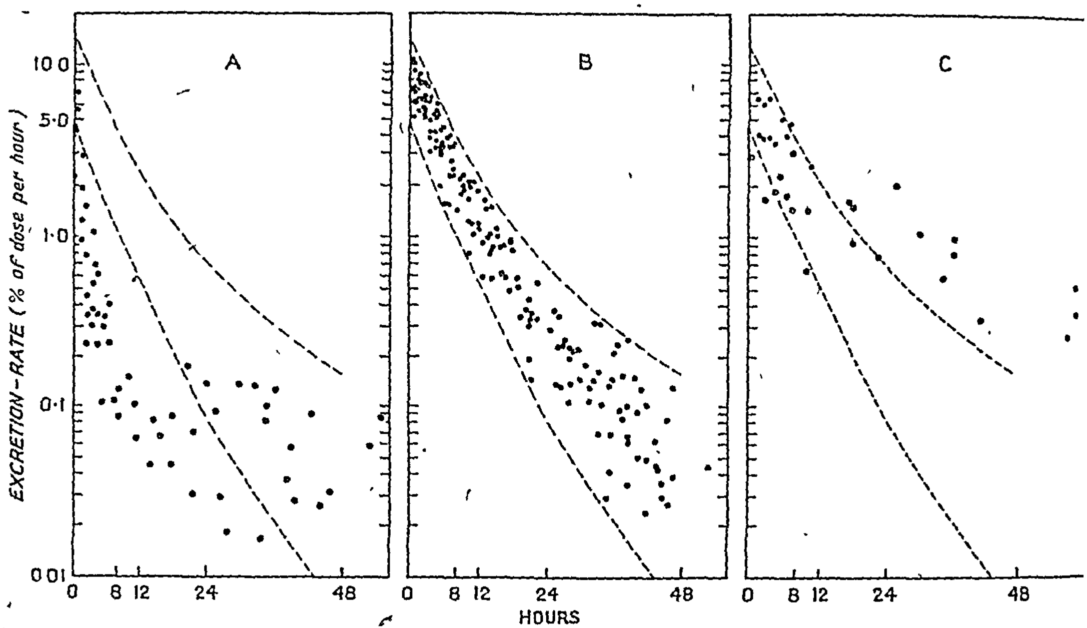

Fig. 2—Results of the radioactive-iodine tests in the three groups studied: A, thyrotoxic patients; B, normal me
C, hypothyroid patients. The results of the test on each person were obtained as for fig. 1, and each single observati
of the rate of excretion has been plotted as a dot. The area enclosing the normal observations (B) has also be
outlined in A and C.

made up to the mark with distilled water and, on shaking, the transient reprecipitation of silver iodide is reversed. An aliquot of this solution is then measured in the counter. The specific gravity of the solution will be 1·177. The density correction required will vary with the type of counter used. With the Twentieth Century Electronics counter type M.6 the observed counting-rate must be multiplied by 1·05 before comparing with the standard.

The counter tube is washed with a solution of sodium iodide (30 g. per litre) which is sufficient to dissolve traces of silver iodide precipitated in the annulus of the counter.

SELECTION OF CASES

Normals

Three groups were selected:

(1) A group of 10 normal male doctors, aged 24–37, who were in good health and had at no time had thyroid disease. These were tested while they were engaged in normal hospital routine duties.

(2) A group of 10 male patients, aged 24–47, who had not previously had thyroid disease and were not in hospital because of endocrine disorder. They were ascertained to be afebrile, with normal erythrocyte-sedimentation rates and no renal disease, and had not received thyroid, iodides, anti-thyroid drugs, or sulphonamide before the test.

(3) 10 normal women, aged 22–60, including 5 hospital workers in normal health and tested at work, and 5

drugs, except 3 who had received
thiouracil some months previously.

All these patients had a raised ba
(B.M.R.) ranging from + 18 to + 74%
the goitre was 3 times the normal gla
the gland was estimated to be $1^1/_2$–2
size. Two patients had heart-failu
none had manifest renal disease. The
were: exophthalmic goitre, 14; toxic
recurrent toxic goitre, 6 (3 after oper
thiouracil).

HYPOTHYROIDISM

The 3 patients tested were chosen a
of hypothyroidism. Two patients,
had developed spontaneous hypothyr
probably primary, since no evidence
injections of thyrotropic hormone wa
patient, aged 33, had secondary hypo
anterior-pituitary necrosis following p
rhage. The B.M.R.s of these cases were
— 29%, the blood-cholesterol levels w
400 mg. per 100 ml., and all the e
showed changes typical of hypothyroid

The subsequent clinical course and re
of the patients with thyrotoxicosis an
has confirmed the initial diagnosis.

RESULTS

ıpare the main characteristics of the three thyroid activity, frequently sampled urinary rates of I^{131} were first studied. The mean rate during the time of collection of each as plotted against the mid-time of the period Since the collections were frequent, this gives pproximation to the true excretion-rate. For ndicated shortly, it then appeared that the ificant data for routine use were the fractions during the intervals 0–8, 8–12, 12–24, and ours from administration of the dose. The e therefore also presented in this form.

the tests were repeated on 3 normal men woman with hypothyroidism they showed a ory correspondence (table I).

Thyroid Function

cretion-rates for 10 people are shown in fig. 2B, result for a typical person in fig. 1. It will be t the decrease of excretion-rate with time is exponential, and that the group as a whole is ompact. There is no significant difference the results obtained with the 10 men in good nd at work, the 10 male bed-patients without disease, and the 10 women with normal thyroid (table II). It therefore seems that the excretion differ significantly between the sexes and is not bly influenced by moderate exercise. Further, us correlation was discerned between the amount e excreted in 48 hours and the volume of urine l or the age and weight of the subject.

xicosis

excretion-rates for the 5 patients studied are in fig. 2A. These excretion-rates decrease more than those of the normal persons during the hours, and between the 8th and 12th hour they hest from the normal range. From the 24th to h hour the observations tend to lie within the overed by the normals.

Hypothyroidism

The excretion-rates of the 3 patients tested are initially normal but decrease more slowly, with the result that only after 24 hours are they clearly above the normal range (fig. 2C).

CHOICE OF URINARY SAMPLES FOR A SIMPLIFIED TEST

Study of the excretion-rates shows that excretion in patients with thyrotoxicosis differs most widely from that in normals during the period 8–12 hours, while the few observations in hypothyroidism show the greatest difference from normal excretion during the period 24–48 hours.

The labour involved in this test comes mainly from the number of samples to be estimated. It therefore seemed that the different characteristics of thyrotoxic and hypothyroid patients could be most economically demonstrated by collecting the urine into four samples, excreted during the periods 0–8, 8–12, 12–24, and 24–48 hours. The percentage of the dose excreted during these periods by the 30 normals, 26 thyrotoxic, and 3 hypothyroid patients is shown in table II and fig. 3. The mean excretion of the thyrotoxic patients between the 8th and 12th hours is only a tenth of the mean for the normals during the same period. Between the 24th and 48th hours the mean excretion of the 3 hypothyroid patients is five times that of the normals.

DISCUSSION

The evidence now available suggests that changes in thyroid secretion sufficient to produce a typical clinical syndrome are accompanied by equivalent changes in the thyroid's avidity for iodine. This would be expected, since iodine is one of the essential constituents of the thyroid hormone.

The inactive thyroids of hypophysectomised animals collect less iodine than normally (Leblond and Sue 1940, Leblond 1944), and the overactive glands of animals previously injected with thyrotropic hormone (Hertz

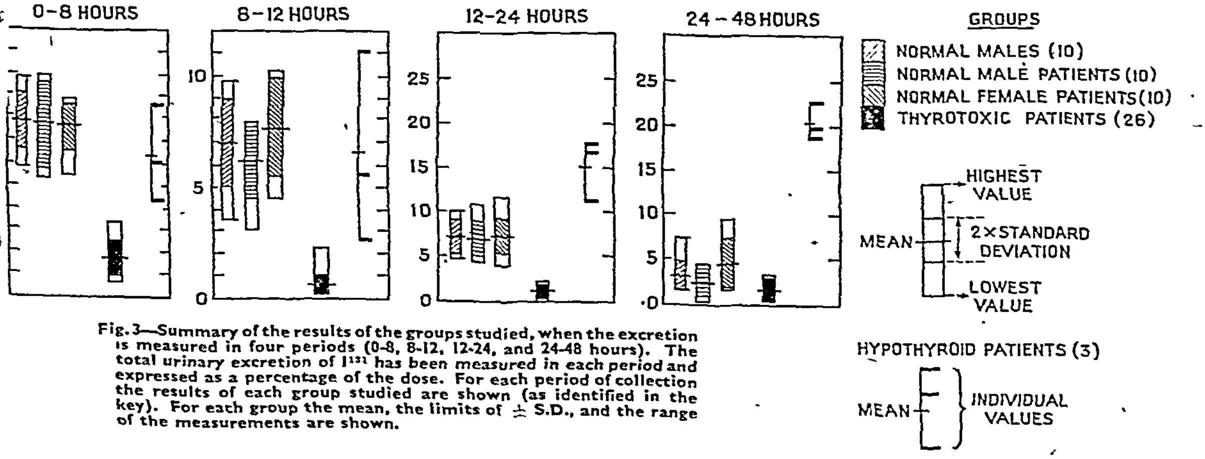

Fig. 3—Summary of the results of the groups studied, when the excretion is measured in four periods (0-8, 8-12, 12-24, and 24-48 hours). The total urinary excretion of I^{131} has been measured in each period and expressed as a percentage of the dose. For each period of collection the results of each group studied are shown (as identified in the key). For each group the mean, the limits of ± S.D., and the range of the measurements are shown.

et al. 1938, Hertz and Roberts 1941, Keating et al. 1945, Leblond and Gross 1948) or exposed to cold (Leblond et al. 1944) collect much more iodine than normally.

Stanley and Astwood (1949) have shown that in normal man the injection of thyrotropin is followed by an increased uptake of iodine. The available clinical measurements of the uptake of radioactive iodine by the thyroids of patients with clinically definite thyrotoxicosis or definite hypothyroidism have given abnormal results in these conditions, an abnormally rapid and high uptake being found in hyperthyroidism and an abnormally slow and decreased uptake in hypothyroidism (Hamilton and Soley 1939, Hertz et al. 1942, Hertz and Roberts 1942, Hamilton et al. 1943, Rawson et al. 1944, Keating et al. 1947, McArthur et al. 1948, Skanse 1948, Werner et al. 1948a and b, Pochin 1948). These observations, though very encouraging, do not indicate whether all clinical abnormalities of thyroid function show a measurably abnormal uptake of radioactive iodine, or whether any other conditions, such as clinically non-toxic goitres and non-thyroid disease, will produce such abnormalities. We are now examining these questions.

Precautions must be observed both in interpreting the percentage uptake of tracer dose of radioactive iodine as an index of the thyroid's avidity for iodine and interpreting that as an index of thyroid secretory function. Clearly the proportion of an administered tracer dose which reaches the thyroid will depend not only on the thyroid's avidity but also on the concentration of iodine available in the body fluids when the tracer is added. Iodine excess due to iodide administration, or when too much carrier iodide is administered with the tracer dose, may lead to an apparently defective uptake. However, where there is no reason to suspect an abnormal intake or loss of iodine by the body, an alteration of the uptake of radioactivity by the thyroid can probably be interpreted as due to a correspondingly abnormal avidity of the thyroid for iodine. Our results with the test show that iodine intake in the diet does not ordinarily vary sufficiently to invalidate this measurement of iodine uptake, for the people we studied were not specially selected and their diet probably varied over the range likely to be encountered in this locality at the present time.

Drugs such as the thiouracil series, thiocyanates, and thyroid extract greatly interfere with the thyroid's uptake of iodine. It is probably not a serious limitation that radio-iodine excretion should only be used as an index of thyroid function when such drugs have not been administered recently. However, Stanley and Astwood (1948) have shown that the reduced uptake of radio-iodine by the thyroid after thiouracil has been given can still be measured and used as an index of thyroid activity; the difference between the thyrotoxic and the normal similarly pretreated with thiouracil, however, is probably too small to be demonstrable except by direct measurement over the thyroid, such as they used. Rawson et al. (1944) found an increased uptake of radio-iodine by a patient who had myxœdema and a goitre, both due to administered thiocyanates. No data are available of the uptake by normal human thyroid glands under less protracted administration of thiocyanate to elucidate this anomalous finding, but it is not likely to be necessary to measure thyroid activity under these conditions. Administration of thyroid extract suppresses thyroid activity and so thyroid uptake of radio-iodine. Skanse and Riggs (1948) have reported pseudothyrotoxicosis due to self-administered thyroid; the clinical signs of thyrotoxicosis were associated with a high B.M.R., but with a low uptake of radioactive iodine. Such an unusual association correctly suggested that the source of excess circulating thyroid hormone was exogenous. Thus a low thyroid uptake of iodine associated thyrotoxic picture should suggest previous administration, while a high thyroid uptake associated with myxœdema should suggest administration of thiocyanates.

There are further disadvantages when the rô thyroid is inferred from observations on the Renal disease, heart-failure, and œdema influence both the uptake of the labelled dos thyroid and its excretion by the kidney. W factors can alter the excretion sufficiently to this test is now being investigated; preliminary tions are that the influence of these factors at least in cases where the test might be required. the measurement of the urinary excretion of *dose of radio-iodine can give only an index* of uptake, it has several practical advantages ov measurement of the uptake of radioactivity thyroid gland. If the thyroid uptake is observed 25 microcuries or more of I¹³¹ must be used and tions made at times dictated by the test; more apparatus is necessary, and it is difficult to record obtained. On the other hand, observ the urine can be made after giving only 10 of I¹³¹ and do not disturb the patient. The ments can be carried out rapidly, accurately, ease at times convenient to the operator. The of urine is a familiar procedure but subject familiar errors unless special care is tak creatinine can be estimated as a check on the of collection.

Our observations on the urinary excreti general agreement with those already availabl et al. 1947, McArthur et al. 1948, Skanse 194 et al. 1948a and b). Though their results entirely translated into the form in which ours presented, table III compares their values o normals.

The slightly smaller excretion found by We (1948a and b) and ourselves might be due to carrier dose, geographical differences, or the cr for selecting normals. The range of norm studied by McArthur et al. (1948) was rather included patients with extensive neoplasti Their series also included persons receiving lar thyroid, which might explain some of their h The overlap of their thyrotoxic and hypothyr *into the normal range* may well be due characteristics of their "normal" group; overlap was found by Werner et al. (1948a Skanse (1948).

Further study of more cases of hypothyro of milder thyroid disorder is required before t of this test can be appraised. It is clear from that, provided the urine collections are acc test is more sensitive when the 48-hour co subdivided; and we find that four subdiv sufficient. Thyrotoxicosis is best revealed excretion in the 8–12 hour period, and hypo by that in the 24–48 hour period, and poo samples with others decreases the sensitivi test.

Keating and others (1947) have suggested matical treatment of the curve of urinary over 72 hours, which permits estimation of th rates of removal of I¹³¹ by the thyroid and by t We have found that our results conform to th only for about the first 10 hours of the norm and for as little as 4 hours of some hyperthyr When the analysis is confined to so short a pe two serious disadvantages: it is impossible sufficiently frequent urine samples with accu results from only the early part of such a curve

precisely. In view of these objections we
forgo the advantage of having an index of
tivity independent of renal function in favour
hod we have described.

ing out such a test as this the radiation hazard
borne in mind, for the long-term effects of
are not yet fully known. When radioactive
given, the thyroid receives by far the most
radiation. The approximate radiation dose
to this gland can be calculated from an estimate
s and knowledge of the fraction of the radio-
reted in the first 48 hours (Hertz 1948); in the
n it is assumed that the rest of the radio-
distributed uniformly throughout the thyroid.
ssumption, if 10 microcuries of I^{131} is given and
reted, a gland of mass 20 g. receives about
lf of this during the first week. In the same
walls of the bladder and kidney pelvis receive
)1 r and the blood about 0·004 r. This thyroid
s considerably greater than the dose-rate of
day which has been agreed as the permissible
ody exposure for workers exposed over an
period (Ministry of Supply 1949). It is,
comparable with the dose delivered in routine
ic X-ray procedures. For instance, Martin
stimated that in the course of a barium-meal
tion the skin receives an average of 5 r per film
and 10–20 r a minute during screening, so with
s and two minutes' screening 45 r would be
l to the skin; thus the thyroid tested as described
receives radiation about equivalent to that
by the skin during a barium meal. Many
s have used 100 microcuries or more of I^{131}
r tests, but we feel that such large doses should
led in diagnostic procedures.

SUMMARY

urinary excretion of I^{131} has been followed for
s after the administration by mouth of a tracer
10 microcuries of I^{131} with 10 µg. of potassium
30 normal adults, 26 adults with obvious
xicosis, and 3 adults with obvious hypothyroidism
udied.

ated tests on 4 persons have shown close
ent.

e was no evidence of correlation between the
excretion of the I^{131} and the patients' sex, age,
ght, or with moderate variations in exercise during
t, or with the volume of urine excreted.

parison of the three main groups of normal,
oxic, and hypothyroid has confirmed previous
ations that the rate of fall of urinary excretion
f I^{131} gives an indirect index of thyroid activity.
ple and sensitive differentiation can be made
en these three groups by measuring the urinary
ion in the four periods 0–8, 8–12, 12–24, and
hours. Thyrotoxicosis is then best characterised
w values in the 8–12 hours period, and hypo-
idism by high values in the 24–48 hour period.

ther experience with this test is required, particu-
in cases of mild thyrotoxicosis and hypothyroidism,
f renal and circulatory disease.

TRANSORBITAL LEUCOTOMY

SOME RESULTS AND OBSERVATIONS

JOHN WALSH
M.B. N.U.I., D.P.M.
DEPUTY MEDICAL SUPERINTENDENT, TONE VALE
HOSPITAL, TAUNTON

TRANSORBITAL leucotomy, a modification of the conventional leucotomy of Moniz (1936), was first adopted by Fiamberti (1937), who pierced the skull through the superior orbital plate. Fiamberti (1947) recommends this operation because of its convenience as opposed to the restrictions which a potentially dangerous operation of the Moniz type imposes. Early in 1946 Freeman (1948), in America, operated by this method with promising results. He introduced it to this country at the Burden Neurological Institute, Bristol, in July, 1948.

Briefly, the operation consists in passing a pointed shaft through the superior orbital plate to a depth of about 5 cm. in the brain and, by moving this instrument from side to side, cutting the white matter in the prefrontal area. The objective is the connexion between the thalamus and the anterior prefrontal area. Meyer et al. (1947), from an analysis of retrograde degeneration in the dorsal medial nucleus of the thalamus, concluded that the central part of the pars parvicellularis—i.e., the main part of the dorsal medial nucleus—projects on to cortical areas 9 and 10 of Brodman. These are the areas which transorbital leucotomy is designed to isolate (Freeman 1948).

I report here some observations on the operation of transorbital leucotomy and the results obtained in eight women 9–10 months after operation. The technique used was, in the main, that described by Freeman (1948). Electroconvulsive shock as an anæsthetic was, however, abandoned after the first two cases, except in case 7, where it was used for demonstration purposes at a meeting of the south-western division of the Royal Medico-Psychological Association.

Early in the series it was found that the rounded shaft of the leucotome tended to become firmly fixed in the orbital plate, and for this reason a modified leucotome was used towards the end of the series. This consisted of a flattened oval blade 18 cm. long, tapering to a fine point with a slight bevel. It was marked at 4 cm. and 7 cm. from the tip. It was 4 mm. wide and 2 mm. thick at the 7 cm. mark. This leucotome pierced the orbital plate more easily, and there was very little resistance to its movement from side to side.

There were no postoperative complications of any importance and the only visible sign of operation was swelling and discoloration of the orbital tissues which disappeared in 7–10 days.

The patients were aged 33–72, and all were in a chronic stage of psychosis: schizophrenia 5, agitated

melancholia 2, and chronic mania 1. No postoperative improvement can be recorded in any of the cases. Two patients died of intercurrent disease 6 and 8 months after operation, and their leucotomy lesions were examined.

LEUCOTOMY LESIONS

Case 1.—A woman, aged 62, with agitated melancholia, underwent operation under thiopentone anæsthesia on Sept. 12, 1948, and died of acute pneumonia on May 9, 1949. Dr. Turner McLardy reported as follows:

"The well-fixed brain showed no external abnormality beyond moderate anæmia. Examination of the orbital prefrontal regions revealed a leucotome entry slit 4 mm. broad in rostral parts of the middle orbital gyri in either hemisphere. The left one was centred 2·9 cm. from the midline; the right one 2·7 cm. from the midline. A transverse section of the left hemisphere perpendicular to gyrus rectus and 0·5 cm. posterior to the entry mark revealed a slit-like lesion of the same dimensions as the entry mark situated in the digital white matter of the inferior frontal gyrus, 1·8 cm. from the midline. A parallel section 7 mm. more posteriorly revealed a lesion of the same length, but now of 1 mm. cystic breadth, situated in the digital white matter of the middle frontal gyrus, 1·6 cm. from the midline. This lesion terminated some 3 mm. more posteriorly in the cortex of the superior frontal sulcus, at the level of the rostral tip of the genu corporis callosi, and 4 mm. rostral to the tip of the anterior horn of the lateral ventricle. The lesion on the right side was practically identical in position, extent, and dimensions, likewise remaining almost parallel to the midline and showing no macroscopical evidence of a sweep through the central white matter."

Case 2.—A woman, aged 34, with schizophrenia, underwent operation under thiopentone anæsthesia on Sept. 12, 1948. She was transferred to another hospital "not improved" 2 months later and died there of myocardial degeneration on March 20, 1949. Dr. R. M. Norman, of Stoke Park, Bristol, examined the leucotomy lesions and found much the same as did Dr. McLardy. There was a leucotome track extending 5 cm. in length towards the genu corporis callosi and parallel to the midline. On the right side there was no evidence of fanning out and the track showed a cystic breadth of 1–3 cm. On the left side there was a similar but broader track, reaching 8 mm. cystic breadth at 3 cm. depth. This was the nearest approach to fanning out.

As a result of his findings, Dr. Norman asked whether the frontal poles on being transfixed (at least on the right side) moved with the leucotome or if the fibres were compressed and not cut by the leucotome. The macroscopical appearances in both these cases suggest that something of this kind happened. Maxwell (1945) states that the elasticity of different brains varies. Operations on the cadaver may be misleading.

The evidence so far suggests that transorbital leucotomy does not sever the white fibres in the anterior prefrontal area as anticipated. In these circumstances it is difficult to understand the clinical improvements claimed as a result of this operation.

It seems that to cut the white matter of the prefrontal area by the transorbital route, a leucotome somewhat on the lines of the McGregor-Crumbie instrument will be necessary. This has the advantage of exerting pressure in the opposite direction while cutting and thereby prevents the brain moving with the leucotome.

CONCLUSION

In the present series of eight cases no definite clinical improvement followed transorbital leucotomy. The necropsies on the two patients who died of intercurrent disease showed that the operation had not achieved its purpose of cutting the white matter of the prefrontal areas. Though the transorbital approach to the prefrontal area is easy, the future of transorbital leucotomy depends on further modifications designed to ensure the greatest possible severance of white fibres in this area.

My thanks are due to Dr. K. C. Bailey, medical superintendent, for permission to undertake this work and for encouragement; Mr. H. E. Pearse, surgeon to the and Somerset Hospital, for surgical suggestions design of a modified leucotome; and Dr. S. R anæsthetics and help in various ways.

PERFORATION OF INTESTINE FISH-BONE

ERIC H. TRAVERS
M.B. Edin., F.R.C.S.
SURGEON, TEES-SIDE HOSPITALS

IT is remarkable, in view of the probable with which sharp indigestible foreign bodies are how seldom these appear to perforate the Macmanus[1] collected 95 cases from publishe and his own experience, nearly half of which to metallic objects; bones, mainly fish-bones, for the next largest group. He found that cæcal region was the site of perforation in thre of the cases and discussed the pathology and th fall in mortality in the present century.

Probably a considerable number of such cas reported, and it is partly with a view to the experience of other surgeons that I following case.

A man, aged 42, seen in consultation at his home, of a continuous pain of 24 hours' duration, with stabs, in the right iliac fossa. There had been abdominal pain, no true colic, no nausea, and no His appetite had been normal despite the pain. been no bowel or urinary abnormality.

He was very tender in the right iliac fossa, was well-marked muscle-guarding in that area. examination was completely negative. The te pulse-rate, and respiration-rate were all normal. was clean. It was clear that there was acute in within the peritoneal cavity, and acute appen provisionally diagnosed. The patient was admitted and operated on $1^1/_2$ hours later.

Operation.—The abdomen was approached thro iron incision carried into the rectus sheath. Whe toneum was incised, the peritoneal cavity in the fossa was found to be entirely obliterated by delicat adhesions. A finger was inserted and was pricked by something lying medial to the cæcum dissection showed this to be the point of a sle lying within the terminal ileum and projecting wall. After isolation of the area the point was grasp object pulled through the bowel wall, which was Appendicectomy was performed and the abdo without drainage. Convalescence was uneventf patient was discharged home on the twelfth po day.

The patient, closely questioned about the possil having swallowed anything such as a fish-bone, said ally that he could not remember ever having anything unusual at any time.

I am indebted to Prof. E. A. Spaul, of the d of zoology in the University of Leeds, for the report on the foreign body: "It appears to ray from a bony fish (cod, salmon, turbot, is very probably from the outer edge of one of possibly a dorsal fin—or from the tail, but n the former. These rays consist of proteins o keratin nature. It is possible that the fish wa preparation for the meal and the sharply po of the ray pierced the gut wall; otherwise t might have been more acute."

Reviews of Books

ıl Malformations of the Heart

s B. Taussig, M.D., associate professor of pediatrics, Hopkins University. New York: Commonwealth London: Oxford University Press. 1947. 8. 55s.

Taussig is well recognised for her work on cya- t-disease. In this long and well-produced work. of congenital cardiac abnormalities are con- ı detail. Her detailed clinical observations and studies have greatly advanced the radiological ıion of these cases. Diagrams and radiograms the features of each condition. and helpful ıgrams demonstrate the circulatory alterations. little reference to kymography or cardioangio- though their recent development has been nspired by Dr. Taussig's work. But as she ıt, most of the diagnoses can be established on and radiological grounds. A short chapter surgical correction of some of the malformations. ıdes the principles and results of the operation the names of Blalock and Taussig. James classic little monograph on congenital cardiac ations does not seem to be mentioned in the s: but such minor criticisms apart there can ng but praise for the observation and knowledge d by the author of this book.

durch Hypnose

Lothar Fresacher, of Graz. Vienna: Maudrich.). Pp. 45. Sch. 6.

osis as a method of psychological treatment come associated almost exclusively with the ıal nervous disorders. Dr. Fresacher holds that y are the mentally healthy usually the best s for hypnosis but it can achieve its best results id to symptomatic treatment in chronic physical He also describes its use as the principal method oach to psychosomatic illnesses. The failure of is to substantiate the excessive claims made by f its exponents. as well as the discovery and ment of the psycho-analytic and related tech- has diverted medical men from this method, in f the striking results which are to be obtained in ases. Patience and continued practice are necessary the best results. and the case is put for the oment of medical hypnotism as a specialised not of psychotherapy but of medicine, and for reference to its use in the student curriculum. esacher's views on the indications for hypnosis ven in detail. and his description of its use in onditions as inoperable cancer, heart-disease. and c eczema, and as an analgesic in childbirth. are ılarly interesting. In conditions in which there ge psychogenic factor, such as impotence, nervous œa. and functional amenorrhœa. he advocates e of suggestion alone after full physical examination. echnique described is entirely orthodox and free theatricality, and in spite of his enthusiasm he s a sense of proportion towards his subject. His opathological views are open to criticism. but in he brings refreshing originality and common to this hackneyed subject.

s is a short readable book in which the arguments early expressed, and it will be of interest to the al physician seeking to take a wider view of his ct.

Mind in Action

ric Berne, M.D. London: John Lehmann. 1949. p. 348. 15s.

. Berne's book is rather more lively than the ntional exposition of psycho-analysis without ; but it is no more easy for the tough-minded ic to accept. Taking a leaf out of the allegorists' , he gives the characters in his case-histories signifi- names: Rex Bigfoot is in trouble with his Œdipus em; Wendell Meleager dreams frequently that he l his mother's brother: and others with names bscure as they are quaint—Ludwig Farbanti and Don Chusbac. Philly Porenza and Simon Seifuss—titillate the reader's curiosity as though he were reading a roman-à-clef. It is a pity that Dr. Berne has not been as explicit as his great forerunners: there was no doubt as to what Sir Epicure Mammon stood for, or Mr. Facing-Both-Ways. The book contains some practical advice. adapted for the English reader. on how to choose a doctor for nervous disorders; there is also a series of appendices on extrasensory perception, intuition (in which. from the example given. the author is evidently endowed much beyond the common run of mankind), and other such phenomena, as well as on "man as a political animal."

Le traitement des tumeurs malignes primitives du maxillaire supérieur

Marcel Dargent; Marcel Gignoux; Jean Gaillard. Paris: Masson. 1948. Pp. 216. Fr. 500.

The preface of this book is written by Prof. Leon Berard. who traces the history of the treatment of cancer of the maxilla. pointing out that it can be divided into two periods—before and after 1900. The first resection was performed by Gensoul at Lyons in 1827. Since 1900. operative technique, anæsthesia. irradiation, and antibiotics have altered the outlook for some of these patients. In the Anticancer Centre of Lyons the authors have treated a large series of cases. and they present a very complete study of this disease. They develop their theme logically. starting with the anatomy of the part and a detailed consideration of the malignant tumours of this region. The various methods of treatment are discussed. including all the types of surgical excision. electrocoagulation. irradiation, and combined surgical and irradiation treatments. The authors advise a block dissection of the regional lymph-nodes in the neck. as a prophylactic and therapeutic measure. Treatment in a series of 207 cases is reported, and they assess the results of palliative and radical treatments. relating them to the type of neoplasm present. Of 120 patients treated with a view to cure. using various methods. there were 24 survivors at five years (20%). Prostheses receive attention. and the good results obtained are shown in photographs. This is a complete and informative treatise on malignant tumours of the maxilla.

Obesity

Edward H. Rynearson, M.D., F.A.C.P., associate professor of medicine. Mayo Foundation; Clifford F. Gastineau, M.D., fellow in medicine at the foundation. Oxford: Blackwell Scientific Publications. 1949. Pp. 134. 17s. 6d.

This splendid little monograph on obesity contains some 422 references. and in addition advises the reader to read articles by four other authors—a kindly but unnecessary gesture. The book, as the preface explains, is more for the practising physician than for the investigator. A full chapter has been written on the ætiology of obesity. including its psychological and endocrine factors. Contra-indications to weight-reduction are discussed. A very full chapter on dieting is given, and this is rightly considered the most important therapy. though some drugs are mentioned. A method for predicting weight loss is described in detail. This excellent custom, commonly followed in America and rarely in this country, is a real factor in helping the patient to adhere to his dietary programme.

Die Angst des Kindes

Marguerite Loosli-Usteri. Berne: Huber. 1948. Pp. 164. Sw. fr. 15.

Dr. Loosli-Usteri. an educational psychologist on the staff of the Institut Jean Jacques Rousseau in Geneva, has here set herself to unravel the skein of anxiety which often torments the normal as well as the maladjusted child; she seeks also to examine the ways in which adults can help the child by means of education and psychotherapy in his struggle against anxiety. Further than this. she considers the positive function which fear fulfils. Dr. Loosli-Usteri believes that she is at variance with Freud in her view that anxiety is an irreducible datum of psychic life, but it seems doubtful whether she has grasped the development of psycho-analytic theory on this matter. She finds in Janet's observations on anxious adults a close correspondence to her findings in maladjusted children. She has used the children's spontaneous utterances, their play, drawings, fantasies, and remarks during an interview: she has also drawn on her exceptionally thorough experience with the Rorschach test, applied to children. Her book provides a valuable study of a fundamental problem in the psychology and psychotherapy of childhood, and has the merit of being free from complicated theoretical preconceptions.

La Fecondazione Artificiale nella Donna (Milano: Istituto La Casa. 1949. Pp. 100. L. 150).—In this booklet by Sebastiano di Francesco artificial insemination, whether A.I.H. or A.I.D., is utterly condemned on religious, ethical, psychological, and juristic grounds; and everything is said to be wicked that deviates in the slightest from the usual mode of coitus.

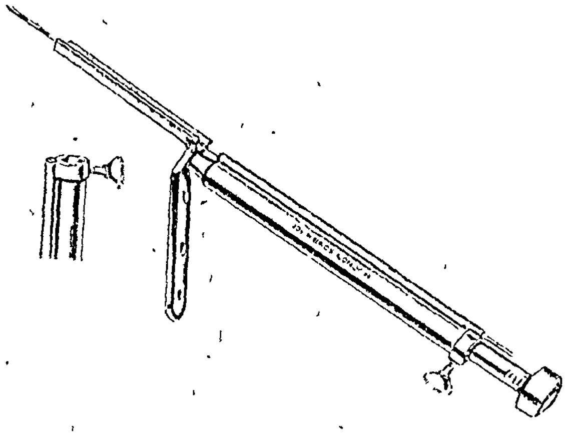
Medical Etymology (Philadelphia and London: W. B. Saunders. 1949. Pp. 263. 27*s.* 6*d.*).—Prof. O. H. Perry Pepper gives here the derivations of words used in medicine, under the separate headings of preclinical subjects (subdivided into anatomy, physiological chemistry, physiology, pathology, bacteriology, pharmacology and therapeutics, and parasitology), clinical subjects (subdivided into medicine, surgery, pædiatrics, neurology, gynæcology and obstetrics, ophthalmology, dermatology, otolaryngology, psychiatry, and radiology), and dentistry. It is difficult to see what is gained by this arrangement, which makes necessary the addition of an index of more than 25 pages. Eponyms, except for general remarks on them, are rightly disregarded in a work of this sort, which deals strictly with etymology and not with the present meanings of the words.

New Inventions

GUIDE IMPACTOR FOR USE WITH CAPENER-NEUFELD NAIL

INSERTING a nail plate (Capener-Neufeld pattern) for the treatment of a pertrochanteric fracture of the femur is not always easy, because the nail, not being cannulated cannot be inserted over a guide wire, as in an ordinary nailing operation. It is also difficult to make a nail plate so that the punch attached for insertion and the nail are in the same straight line. Usually the screw-hole for the attachment of the punch is about $^1/_4$ inch below the apex of the V of the nail.

The guide impactor here illustrated, which has been made by Messrs. Down Bros. and Mayer & Phelps Ltd., overcomes these difficulties and allows the nail plate to be inserted along a guide wire. The impactor consists of two tubes of different diameters welded together—a larger, corresponding to the diameter of the punch, and a smaller, the diameter of which is that of the guide wire. There is a fixation screw on the larger tube to attach the guide firmly to the punch.



The guide wire is inserted in the usual way. The nail with punch attached and the guide in position is then slid on the guide wire. When the nail is being in, it is necessary to depress the punch towards to keep the point of the nail in contact with th wire.

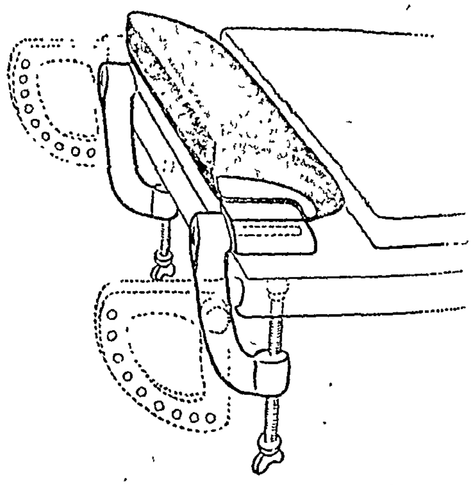
SACRAL REST FOR USE IN SYNCHRO COMBINED EXCISION OF RECTUM

THE synchronous combined technique is method of choice in many centres for pe abdominoperineal excision of the rectum. An condition for the smooth conduct of this operation accurate fixation of the patient to the table lithotomy-Trendelenburg position by means of leg supports such as those devised by Lloyd which ensures for both abdominal and perineal o satisfactory access to their respective operation Particular importance attaches to the precise of the sacrum relative to the end of the table; it be so situated that the sacrococcygeal joint about an inch clear of the table—no more and no It is further customary to raise the sacrum on a m sized sandbag with the object of flattening the lumbar lordosis and tilting the pelvis upwards to the perineal dissection.



Several disadvantages, however, attach to the a sandbag for this purpose. First, it provides a sin hard support for the thinly covered sacral pro Secondly, unless special care is exercised it is lia be knocked off the table on to the floor as the pat pulled down into correct position before the start operation. And thirdly, even though the shoulde firmly supported it may slip slightly towards the end of the table when the patient is tipped into Trendelenburg position, which may confront the p operator with exceptional difficulties. Attempts the sandbag to the end of the table and counter latter two disadvantages have not been very succ and I believe that a better plan is to use a sp designed metal sacral rest such as that shown in accompanying figure.

This rest can be firmly fixed to the tail end of the by strong screw clamps so that it becomes insep from it for the duration of the operation and yet quickly detached when the operation is completed sloping convex surface is upholstered with 'S rubber and provides a comfortable bearing point f sacrum, while its distal edge is clear cut and sl overhanging, facilitating access to the perineal The rest has been used with satisfaction for over synchronous combined excisions at St. Mark's Ho where it is now regarded as part of the standard e ment for this operation. It was made to my specifi by Messrs. A. L. Hawkins & Co. Ltd., 15, New Cave Street, London, W.1.

foundation of trouble-free weaning

The popularity of Farex is based on sound results . . . practical success as an infant weaning food over many years. Here is a food that provides a sensible balance of protein, fat and carbohydrate; a sufficiency of mineral salts; and adequate vitamin nutrition—all factors of first importance in the infant diet. *Three* cereals are blended in Farex with extra iron, calcium and vitamin D, forming a bland smooth food ideally suited to the young digestion. Indeed, Farex mixed with milk and sugar can be given to babies just as soon as they turn the scales at 15 lbs., even if this happens as early as the fourth month. Farex is ready cooked and is therefore very quickly prepared. It is unflavoured, too, which means that it can be mixed with strained vegetables, bone broth, fruit juices and so on. And, incidentally, Farex is very economical.*

Employment of Elderly Persons

he signs of a civilised community is that it
me of its time and wealth to the proper
elderly members. This work has usually
unobtrusively by the elderly person's
d in general that holds true today, as
has shown in his survey of Wolverhampton.
has been a growing and understandable
t the State should intervene to an increasing
he housing shortage has made the accom-
of aged relations in their families' homes
cult than ever, while, with the shortage
ic help and the greater opportunities for
nt offered to those who would have cared
it has become harder for the elderly to lead
nt lives. In a reasonably stable world it
difficult to refuse more State help, but
esent economic stringency other questions
onsidered. To what extent can the State
give us all a comfortable retirement, and at
should this retirement begin? Under the
w men become eligible for pensions at 65
en at 60. The pension is small—26s. a week
made up of a 10s. old-age pension and a
ment pension. In cases of need the Assistance
n add another 11s. a week, making a total
n income on which only a somewhat austere
ssible. But, as Dr. Fagge points out on
page, if the elderly person decides to
h his work and earns more than £1 a week,
retirement pension is withheld until the age
hen the promise of an extra 1s. a week for each
y contributions paid a sufficient incentive?
Nuffield inquiry,[2] for instance, came the
n that he should receive a lump-sum pay-
ll the pension he has forgone. Many firms
workers retiring when they have reached
ble age, while other employers, including the
ire their employees at 60. The number of
aching pensionable age has risen from some
in 1900 to about 6,000.000 now, and since
every probability of this increase continuing
nated that by 1970 a fifth of the population
ntitled to a pension. The recent increase in
ol-leaving age has removed many potential
from among the younger age-groups, and
ced with the serious question of how long it
ossible for a diminishing number of workers
iddle period of life to support not only an
l number of their younger contemporaries
a steadily increasing number of their elders.
generally accepted, though difficult to prove,
increased expectation of life has been accom-
by an extended enjoyment of health and
vigour, and that among those of pensionable age and over there is a large reservoir of men and women who could still contribute substantially to the nation's wealth. But before discussing the economic implications of this presumption it is necessary to assess the health value of continued work. Those who have worked among elderly patients mostly agree that occupation, provided it is not in excess of their mental or physical powers, is good for the elderly. For example, at Basle it has been found that over 90% of elderly persons who are admitted to the cantonal hospital ask, after a few weeks, to be given work, and for these employment is found, up to their capacity, in the adjoining hospital, where they work as porters, lift-men, cleaners, menders, and so on. They are paid a small wage in addition to their pension, and improvement in their health and morale is the rule. The popularity of occupational therapy in institutions where aged persons are housed is evidence that some form of congenial activity is welcomed even by the very aged, while the medical results are striking. During the late war, when labour was scarce, a large number of elderly workers were retained in industry for several years after their usual retiring age, and reports showed that both the quality and quantity of their work were good, and that their health did not suffer. Since the war some firms have arranged to retain many of their elderly workers in employment, while an interesting experiment of this sort is about to start at Wolverhampton. In America similar experiments are being carried out in several industries, and evidence is accumulating to show that elderly people are often capable of being trained in new work. Useful research into such capacities of the aged is being done by Sir FREDERIC BARTLETT, F.R.S., at Cambridge. In the years between the wars, and before that, large-scale unemployment was endemic in this country, and the trade unions were anxious that the retirement of elderly workers should not be delayed, for they rightly argued that it was preferable for them to retire on pension than for younger workers to be supported by "doles."[2] But now, when the Government has announced its adherence to a policy of full employment, and so far has been successful in carrying out this policy, there is less need for the trade unions to adopt such restrictive practices. The detailed working of any scheme for employing the elderly is bound to be complicated, but with good will on both sides such questions as hours of work, payment, and the promotion of younger men and women should be solvable. Elderly workers will not all be fit to work a full 5 or $5^1/_2$ day week, and it need not be too difficult to arrange their conditions of employment satisfactorily. During the war a considerable amount of work (outwork) "was done by old people in their own homes, and at the beginning of 1944 no less than 30.000 outworkers, about half in the London area, were freeing full-time workers in factories for work which was best done in factories, or which could be better performed in factories."[3] The problem of work in homes, hostels, or hospitals has always been that of finding a market for the goods so made, but one or two successful experiments in marketing by a central body have been carried out, and this practice could well be extended.

J. H. The Social Medicine of Old Age. London, 1948.

nanship of B. Seebohm Rowntree. London, 1947; p. 103.

[3] The Nation and the Aged: a Report of a Committee of Liberals to the Liberal Party Executive.

A recent survey by the Ministry of Labour shows that about 60% of all would-be pensioners continue to work after they have reached pensionable age, but this percentage includes agricultural and other country workers who are well known to go on working until an advanced age and does not state how long these workers continued at their employment, so the value of the survey is limited. It has been estimated that in a few years retirement pensions will cost the country about £500,000,000 a year in unproductive expenditure a sum which cannot be contemplated with equanimity in our present economic state. Nobody wants to reduce the pension rate, but are there the same objections to an increase in the length of working life? This latter alternative must be combined with the strict proviso that no-one of pensionable age shall be compelled to work if they do not wish to and that no employer shall be compelled to employ an elderly person whom he does not consider fit for work. The *Times* of Aug. 29 says: "there is no doubt that the movement towards earlier retirement ought not to be talked of for the time being and that all provisions affecting the employment of the elderly need to be reconsidered." When medical opinion is so closely paralleled by economic necessity, would it not best serve the interests of people of all ages to offer our younger pensioners stronger inducements to keep busy a little longer?

Whooping-cough: Prevention or Cure?

WITH the passing of the major pestilences—smallpox, typhus and plague, typhoid and cholera—from our country, more attention is rightly being given to control of the common childhood fevers. Of the four most important, scarlet fever is now a mild infection, diphtheria is being rapidly brought under control, and deaths from measles have declined sharply in the past quarter of a century. Whooping-cough has yielded least to ameliorating measures, and this protracted debilitating infection with its major incidence and mortality in early childhood is today the most challenging of the acute specific fevers. The evidence that whooping-cough is caused by *Hæmophilus pertussis*, of which all strains are apparently antigenically identical, and that a clinical attack confers considerable immunity, suggests that the disease could be prevented by a vaccine. However, though vaccines have been on the market for many years, there is still doubt and controversy about their prophylactic value. The first step forward was made in 1931, when LESLIE and GARDNER[1] showed that only smooth (phase 1) strains were protective experimentally; and a strong indication that a vaccine made from freshly isolated strains had some protective value was given by the experience in the Faroe Islands, where, in an epidemic year (1929), 25% of the inoculated escaped infection compared with 1·8% of the uninoculated, and infection was classified as moderate or severe in 46% of the uninoculated but in only 2% of the vaccinated group. American workers like SAUER and KENDRICK claimed greater success with larger doses (three or four weekly injections totalling 80,000–100,000 million organisms), but others reported failure.[2]

A difficulty in assessing the value of an
lactic or therapeutic agent is to provide a
untreated controls, identical, as far as is
possible, with the treated group. The first
of this kind in Britain, done on nursery c
a British vaccine, failed to show any protec
so, at the request of the Ministry of Health
Research Council committee organised
controlled trials in different areas of E
Wales, using both American and British
A preliminary statement on the progress of
is published on p. 476. It appears that in

ive cultures continued to yield *H. pertussis* d after therapy. Toxic effects included ia in about half the cases and pyrexia with ion in most of those given the drug intra- r. The new antibiotics, chloromycetin and in, are both active in vitro against *H. pertussis.* w of their beneficial effect in such bacterial s enteric and undulant fever, it seemed test their therapeutic action in pertussis. others[7] found that aureomycin not only ut also prevented death in mice injected rally with many lethal doses of *H. pertussis,* e effective when given in small doses twice eight days than in larger doses for a shorter n a small group of 20 children with clinical treated at home with a total dosage of kg. body-weight, in divided doses over four ays, the results were distinctly encouraging. response was obtained in those treated in paroxysmal stage, which again emphasises e of early bacteriological diagnosis with or pernasal swabs.[8] Unpublished experi- ork suggests that chloromycetin, which is g manufactured synthetically in this country, ly effective against pertussis, and no doubt ities will be found for testing one, or both, drugs clinically during the coming winter. pects are bright, and perhaps within the ade whooping-cough will have ceased to rifying disease for the mothers of young

Diagnosis of Thyroid Disease

ACTIVE iodine is now being used for the of thyroid disease at several centres in this The tests are based on the facts that iodine ential part of the thyroxine molecule; that highly concentrated by the thyroid; and that id cannot distinguish between the common form (I^{127}) and its radioactive isotope (I^{131}). By ering a minute "tracer" dose of radio-iodine ortion taken up by the thyroid in unit time estimated. There are reasons for assuming proportion indicates the rate at which the is making thyroxine, and also that thyroxine e thyroid at the same rate as it is being made. rate of entry of radio-iodine into the thyroid s an index of the rate at which thyroxine is he thyroid.

ate at which radio-iodine is taken up by the can be measured in several different ways, ave already been reviewed in these columns.[9] the choice is between measuring the rate of of gamma rays by means of a Geiger counter ver the neck, and measuring the amount of ivity in the urine at intervals after adminis- of the radio-iodine. The first method gives ired information more directly; the second measuring the amount of radio-iodine which entered the thyroid and is therefore excreted rine. POCHIN and his colleagues[10] have refined the first method by simultaneously estimating the concentration of radio-iodine in a sample of plasma. By combining this estimate with the data obtained from the counter over the neck, they can calculate a "thyroid clearance-rate," which measures the rate at which the thyroid is removing radio-iodine from the plasma. This procedure is necessarily rather elaborate, but at a meeting of the Royal Society of Medicine in May MYANT and POCHIN suggested two possible variants which might be more suitable for routine work. One of these involves comparison of the counting-rates over neck and thigh an hour after a dose of radio-iodine; the other a single estimate of plasma radio-iodine two hours after administration by mouth. The urinary tests described in the present issue by two groups of workers are also technically simple but have the disadvantage of involving admission to hospital and the accurate collection of urine samples. Each of the existing techniques is capable of demonstrating large differences between normal subjects and typical cases of myxœdema on the one hand and of thyrotoxicosis on the other. To the clinician a really accurate and reliable estimate of the rate at which thyroxine is made would obviously be welcome. But this would not solve all diagnostic difficulties, and indeed it might create a new one: while some of the difficult "borderline" cases would be readily assigned to the normal or the abnormal group, a few would be likely to remain uncomfortably poised between the two. Statistically normal distributions do not have sharp upper and lower limits; at each end of the scale there are a few exceptional individuals who yet must be reckoned normal. On the other hand, there are very wide variations in the severity of thyrotoxicosis, and it seems a likely guess that the mildest cases will have no more active thyroids than a few exceptional normal persons; indeed such an overlap has already been demonstrated with radio-iodine, and its existence is probably no reflection on the technique adopted. There are other grounds for expecting a continuous gradation in thyroid activity, from the normal to the thyrotoxic, rather than a sharp separation into two distinct classes: for clinical experience suggests that patients can react very differently to comparable degrees of thyroid overactivity. The best example is the elderly woman with long-standing nodular goitre and auricular fibrillation; commonly no other sign of thyrotoxicosis is found and the basal metabolic-rate may be only slightly raised or even be wholly normal. In some cases of this type thyroid activity may turn out to be within normal limits. Yet if such patients are treated by subtotal thyroidectomy, regular heart-rhythm is usually restored. Thyroid activity may not have been excessive compared with that of normal people; but it was excessive for the particular patient.

Examples of this sort prove nothing, but they show that we should be wary of accepting the measurement of a single physiological function as an absolute criterion of disease. To have obtained a measure—even an indirect measure—of the rate of thyroxine production is a fine achievement, but until it becomes possible to measure also the subject's responsiveness to thyroxine there will still be a place for clinical judgment.

Annotations

CHANGES IN GENERAL PRACTICE

IN a report to the Minister of Health the Medical Practices Committee for England and Wales has given an account of its stewardship during the first year of the National Health Service. From its favoured position the committee has been well placed to observe the change that is taking place in general practice, particularly as it affects the distribution of doctors. As the following extracts show, the committee is satisfied that a healthy change in distribution is already beginning and is likely to continue without any sanctions other than those imposed by the changed economic situation in districts which previously attracted more than their due share of practitioners.

> "The number of general practitioners in the service by July 5, 1948, was approximately, we understand, 20,000. There had in fact been about 2000 new entrants into general practice in the few months immediately prior to the appointed day. This increase was largely due to the impact of the Act and uncertainty in the minds of the profession. Some genuine concern at the possible activities of this committee was we believe a strong factor in the decision on the part of practitioners to attempt to settle a place of practice before the Act came into force. A natural reaction to this has been manifest during the past year. Some of these new entrants into practice have done well and have succeeded in establishing themselves. Not all were wise in their choice of location. Some of those who chose the more desirable residential regions have been obliged to contemplate and to seek transference to other areas or other employment. The same effect of economic circumstances though to a lesser degree has been noted with established practitioners. Since the appointed day in areas desirable from a residential point of view many retiring practitioners have not been replaced; the three-man practice may have become a two-man practice and the single practice dispersed."
>
> "What it is desired to emphasise is that the impact of the *Act itself and the economic circumstances of medical practice* which flow from it are already exercising an effect upon the distribution of general practitioners in England and Wales. This committee is in a favourable position to assess this movement which is in the direction desired and is being achieved without coercion by any statutory body."
>
> "Partnerships are multiplying and new practices are being started. Difficulty in obtaining suitable premises from which to conduct a practice alone prevents this process from being accelerated. Many assistants have become partners of or successors to their principals and the committee considers that preliminary apprenticeship as an assistant is still the best method of entry into general practice."
>
> "It became evident that in certain executive-council areas, or parts of them, it would be a waste of medical man-power to allow additions to the medical list of the executive council concerned for the purpose of practising in those parts and that such areas should be closed. In a few areas the position was less evident, and the committee felt a decision might well depend upon day to day circumstances and that these areas should be designated as 'doubtful.' The applicants to practise therein would be warned that the chance of establishing themselves in practice was likely to be difficult and that permission to make the attempt would not necessarily follow upon such application; the committee would act upon information before it at the time of the application and might then declare the area closed."
>
> "This committee has never opposed a desire that a replacement should be allowed for a doctor leaving any practice, whether the desire was expressed by an executive council, a practitioner himself, his partners, or occasionally on representations by outside bodies."
>
> "The committee has never refused admission to the list for the purpose of starting a practice against the advice of the executive council concerned or the local medical committee. The committee in carrying out its statutory duty has, however, been compelled to admit applicants to the medical list against the advice of some executive councils that they be refused."

The committee goes on to give some acc
way in which, in conjunction with executi
and local medical committees, it has devised
which vacancies in practices could be

An appendix to the report gives the c
views on the classification of different pa
country into areas which should now be r
"closed," "doubtful," or "open." A fou
(a subdivision of this last section) might
classified as "wide-open," for in it are in
districts where the committee regards the p
more doctors as a matter of priority. The cl
of the various districts has already been
but the committee emphasises that its dec
not immutable.

An accompanying *circular from the* Ministry
upon executive councils the need for urgent
attract doctors to the "wide-open" areas. I
such steps as advertising for a specified r
doctors to set up practice, offering at the
an assurance of the fixed annual payment to
while they are establishing themselves. A gu
this payment will of course be a help to the
newcomer, but the executive councils may
that their best efforts to extend their se
frustrated by the difficulty of finding premise
for incoming doctors. It is in just such area
that the early provision of health centres w
been so useful.

MERCURY HAZARD TO THE POLI

FOR two thousand years cumulative poiso
mercury and lead have had a way of turning
guise of new hazards. In 1823, Purkinje, the
anatomist and physiologist, famous for his wo
cerebellar cortex and on vision, was the first
out that fingerprints could be accurately classi
suggestion that they should be used for perso
fication came much later. A fingerprint burea
up at New Scotland Yard in 1901, and now,
fingerprints are taken from the fingers of su
covering them with printer's ink and pressing
cards. Detection by fingerprints depends on
parison of such inked impressions with latent fi
found at the scene of the crime. Before the
photographed latent fingerprints are developed
dusted with a finely divided powder such as al
willow charcoal, acacia black, lamp black, or
graphite. White lead was at one time used,
tunately it has been discarded, for it has ca

in a policeman who worked with it. In Great
day perhaps 90% of all fingerprints developed
ed with our old friend "grey powder"—
rum cum creta *B.P.*—containing a third by
metallic mercury. It is not surprising that
spend their time, often in confined spaces,
attering such a powder about with a brush or
r should sooner or later show evidence of
nercurialism, and on p. 451 Dr. Agate and
kell report the finding of such evidence among
of the Lancashire Constabulary.

ive Chief Inspector C. Campbell, of that con-
, when looking for a more efficient fingerprint
consulted a scientist friend, who, on hearing
cury with chalk was being used, told him that
was dangerous and put him in touch with Dr.
Hunter's department for research in industrial
at the London Hospital. Agate and Buckell,
bers of the department, investigated matters on
and found that 7 out of a group of 32 Lancashire
n regularly using grey powder had symptoms
s of chronic mercury poisoning. Exposures of
s or more a year at this work appear to constitute
e risk. It is probable that exposures have not
ached this magnitude in other police forces, for
ire lays particular stress on the value of finger-
but other cases will almost certainly come to
Fortunately the poisoning in the cases reported
severe. Prevention should not be difficult, for
wder will now join white lead in the list of
too dangerous for this purpose, and substitutes
ng found. What thousands of years it takes to
me the fact that lead and mercury are cumulative
!

UNIVERSITY TRENDS

946 the Barlow Committee on Scientific Man-
called for doubling of the universities' output of
tes in science and technology. The country's
ic situation is such that the main hope of
g the present standard of living lies in the
ment by technical means of the limited resources
le on this island. Quite apart from national
rations, the medical profession has a vested
in advances in pure science, for each new tech-
r fresh conception of life or matter soon has its
ssions on medical practice. At the university
not disregard the leavening effect of students of
manities on the philosophy and ethics of our often
hnically minded profession.

esponse of the universities to this call for expan-
the post-war period can be gauged from the
account[1] by the University Grants Committee
academic year 1947–48. Since 1945 the student
tion of the British universities has risen by 57%
e pre-war figure—from 50,002 to 78,507. Quality
as quantity is of crucial importance, and the fact
f some 15,000 graduates last summer only 60%
n honours degree has excited some comment. It
en suggested that with the removal of economic
s to university education (80% of Oxford under-
tes are "assisted"), many have been admitted
her studies who are unable to profit from the
tion given. Beyond a certain point—say the
3% on the intelligence-test scale—saturation may
ckly reached and nothing further can be achieved
gets and exhortations.

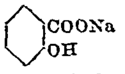
tever the truth of these qualitative surmises, the
itative pattern of post-war trends in university
ion is now clear. In 1947–48 the percentage distri-
of men and women full-time students over the various subject-groups was as follows: men, arts 39%, medicine 21·5%, pure science 19%, technology 16·7%, agriculture 3·8%; women, arts 62·7%, science 17%, medicine 16·4%, agriculture 2·4%, technology 1·5%. In recent years these proportions have been fairly stable. Compared with 1938–39, the arts faculties retain a remarkably constant proportion of the students (45%), but there seems to have been some shift from medicine and dentistry towards pure science which now engages 18·5% instead of 15·3% of the total. In absolute numbers the result of the drive towards scientific studies is even more striking: whereas students of medicine and dentistry have increased from 13,636 to 15,907, science students have increased from 7661 to 14,544.

Within medicine itself the distribution of these 15,907 students is interesting. While Scotland and Wales have 4157 and 326 students of medicine, London with 5844 accounts for more than half of England's total of 11,424. London differs too in its male/female ratio, which is 5 : 1 compared with 3 : 1 in other British universities.

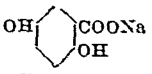
GENTISATE FOR SALICYLATE

The cause (or causes) of rheumatic fever is still undecided, though there is a vast mass of evidence relating it to infection with hæmolytic streptococci. The impressive success of Hench and his associates[1] in treating rheumatism with the cortical steroid, 'Cortisone,' suggests that in the future treatment will be directed to correcting associated metabolic disturbances. Meanwhile, we must make do with remedies that are to hand. Sodium salicylate usually controls the pain and swelling of rheumatic fever; but effective doses almost always produce the well-known toxic effects involving the gastro-intestinal tract and the special senses. It now seems that sodium gentisate is equally effective and produces few, if any, toxic effects.

In vitro, sodium salicylate inhibits the enzyme hyaluronidase, in very high concentrations, while the biological oxidation-product of salicylate, gentisic acid, does so[2 3] in a concentration of a few µg. per ml. In the belief that increased hyaluronidase activity might be responsible for the breakdown of interfibrillar cement in rheumatic disease, Meyer and Ragan[3] concluded that gentisic acid would be worthy of trial in rheumatic fever.



Sodium salicylate



Sodium gentisate

Their results were quite definite. In five patients with acute rheumatic fever sodium gentisate in doses similar to those of the salicylates led to disappearance of pain, swelling, and heat in the joints; a fall of temperature to normal; and a decrease in the blood-sedimentation rate. In one patient withdrawal of gentisate after 3 days' treatment was followed within 44 hours by a return of acute joint symptoms, which responded promptly to renewed administration of the drug. Four patients with persistently active rheumatic fever—so-called "chronic rheumatic fever"—responded equally well to salicylate and gentisate. The two drugs were also equally effective in seven patients with rheumatoid arthritis. In patients receiving as much as 10 grammes of the drug per day, Meyer and Ragan only once observed toxic manifestations—in a patient receiving 8 g. per day who developed some epigastric distress which subsided immediately on withdrawal of the gentisate. None of the patients complained even of tinnitus. One patient

with a chronic duodenal ulcer could not tolerate salicylate, whereas gentisate caused no gastric irritation. Even more striking are the results of Camelin and his colleagues,[4] in France, who have administered up to 18 g. of sodium gentisate without producing toxic effects. They find that the drug does not lower the alkaline reserve and need not be given in combination with bicarbonate.

A SEARCH FOR FOSTER-HOMES

NEXT to adoption, the Curtis Committee[5] preferred boarding-out to any other method of providing a child with a substitute for its own home. They noted, however, some of the reasons why suitable foster-homes are scarce—among them, the dread parents have of becoming attached to a child who may afterwards be taken away, their dislike of interference from the child's own parents, their fear of inspection and criticism, and the small amount of the allowance. Miss Mary Maw, who has just published, under the auspices of the National Association for Mental Health, the results of an experimental search for foster-homes,[6] finds that most of these objections still stand. Her experience was gained in 1947 in a small municipal borough (population 90,000) and its surrounding villages in a rural and thinly populated county, and she compiled a central register of foster-homes. During the eighteen months spent on the experiment 30 children were placed through this register, which was used by voluntary bodies, the public-assistance committee, the health and education authorities, the child-guidance clinic, and the probation officers. At the end of the experiment the children's committee took over the register for the use of their newly appointed children's officer. The study added only 35 new foster-homes to those already in use; and this rather small bag is in itself significant of the unforeseen hazards of the chase.

Many people, it seems, would like to have a child—childless couples, parents who have lost an only child, those with an only child who needs a playmate, those whose children have grown up and left home, those who have had only boys and want a girl or vice versa, single women or widows (often living alone), and comfortable families who feel they could make another child welcome. But these prospective foster-parents much more commonly want to adopt a child than to accept one for boarding-out. Foster-children who have grown dear to their protectors may be removed. Sometimes their own mothers get posts in which they are able to keep them; sometimes a voluntary society responsible for the child may recall him at a given age to enter a training home or residential school. This practice, which has been the cause of much unhappiness, has recently been modified, she says. Only a few foster-parents can face a partial relationship with the child—those, she finds, who "by reason of their own stability and satisfactory adjustment, are able to regard the situation with detachment and refrain from a possessive attitude." Such good parents can give an "unaffected, uncritical, and ungrudging welcome" to visiting relatives; and are in fact more like wise grandparents who do not complicate the child's loyalties, but take him and his situation as they find them.

In most people, however, many unconscious anxieties prejudice the relationship. The foster-parents, romantically longing to pour love out on a child, may overwhelm him with their possessive affection. He rebels, and passes dramatically from the class of ewe lamb to that of serpent's tooth. Perhaps the child is illegitimate:
then every peccadillo may be hailed as the
a bad heredity. Perhaps there is guilt
natural mother deprived of her child: the
feels she has stolen the baby. Perhaps t
parents, unconsciously ashamed of their own
fertility, doubt their capacity for successfu
hood; then, if self-blame is displaced, the chil
the scapegoat. Perhaps the couple, anxious
their only child with a companion, hav
a child of the same age; then the
jealousy between the two children will lead t
fighting.

Nevertheless, when all these drawbacks are
owned, it remains true that many children
good foster-care, and a search for appropri
homes is never wasted labour. As Miss M
"it is not necessarily the most intelligent
happy, warm-hearted people, not afraid of
warm feelings, who make the best foster-
people, that is, who not only feel affection bu
gift of persevering in it.

HE MEDICAL COLLEGE AT BAGDAD

great days of Arabian medicine, Rhazes and taught and practised in Bagdad, and Bach- s paid a salary of some £300 a year for bleeding ing the immortal Haroun-al-Raschid. But, as an says in a report to the committee of manage- the Examining Board in England, the lights when the Mongols sacked Bagdad in 1258, and lighted again until after the 1914–18 war, q ceased to be a backward province of Turkey me an independent country. Lord Moran has iting Iraq on behalf of the board to advise on our Royal Colleges should recognise the Royal of Medicine, Bagdad. His report shows a school full of promise but hampered by the lack ersity, and by the difficulty of attracting good o teaching. Most of the doctors qualifying practise in Bagdad, where rewards are highest, not anxious to work either in the country or in the basic sciences. The cure for this ism (which, Lord Moran reminds us, is by no onfined to Iraq) is to be found, he believes, in y standards and the university spirit.

g 1948–49 there were 296 men and 39 women at the Medical College of Bagdad. About nts now enter yearly, but the wastage is very f 605 students admitted to the school between d 1942, only 212 (35%) graduated; and at only about 40 qualify yearly. The population is 4,500,000, and the number of doctors now on ister 528. If a standard of 1 doctor to 3000 is to be achieved, another 1000 doctors are

One cause of the heavy wastage is the low d of education in the secondary schools, and ese become more efficient the best hope lies in selection of students. At present the medical accepts the Iraq secondary school certificate; but it would be better, Lord Moran thinks, to require prospective medical students to pass a matriculation test conducted by the college itself.

Many of the medical school buildings are modern and well adapted to their purpose, but some need improving. According to law, every newly qualified doctor must serve as a resident for two years: but in practice there are only 15 vacancies for some 40 graduates, and those who fail to get one either join the Army or go into private practice. Some 5 or 6 of the successful 15 are chosen to specialise at the end of their term of office, and to these a ladder of training is open. They become second grade tutors for three years, while working for their M.D. or M.S. If they fail to get one of these higher qualifications they leave and go into practice. Those who succeed become first-grade tutors for three years and must take a specialist examination; on passing this they become assistant-professors, and after eight years' teaching in this rank, if their contributions to medical journals are worthy, they become associate professors. In this office they await a vacancy to be elected professor.

Looking at the work of the college all round, and taking account of the difficulties of the situation in Iraq, Lord Moran recommended the committee of management to advise the Royal Colleges to recognise the medical school at Bagdad for a year; and this the committee has done.

PHYSIOTHERAPY SERVICE

A CIRCULAR issued by the Ministry of Health to hospital authorities indicates the lines on which the provision of physiotherapy should be organised. The circular states:

> "The Minister is advised that the maximum benefit of modern physiotherapy is to be obtained under specialist supervision in fully staffed and equipped hospital departments. Furthermore, the shortage of adequately trained personnel, which will continue for an indefinite period, makes it imperative to concentrate them in hospital departments where their services can be employed to most advantage. Accordingly, physiotherapy in the National Health Service should be provided only under specialist prescription as part of the hospital and specialist service, and responsibility should be accepted by regional boards only for treatment prescribed by hospital specialists and carried out under their supervision. General practitioners who consider that their patients require physiotherapy will normally refer them to a hospital. . . ."

The system formerly in use in some rural areas of contracting with public organisations or with private physiotherapists is to be discontinued and replaced by full-time or part-time clinics in suitable towns or villages, conducted by physiotherapists based on the nearest hospital with an adequate physiotherapy department. These clinics will make use of existing halls or other suitable buildings. Physiotherapists now in private practice may be offered full-time or part-time contracts in the hospital service. Hospitals are asked to give careful consideration to the possibility of appointing blind physiotherapists to vacancies on the staff of hospital departments and associated clinics, particularly any situated near the blind physiotherapist's home.

Evening clinics are to be organised to save loss of time to patients who need treatment though still at work (said to number some 10–15% of the total). Domiciliary treatment will be provided only exceptionally; and hospitals will accept responsibility for such treatment only when it has been prescribed by a specialist.

DR. F. T. REES has been appointed director-general of medical services of the Ministry of Pensions in succession to Sir Francis Prideaux who retires on Sept. 20.

WHOOPING-COUGH PROPHYLAXIS

PRELIMINARY STATEMENT BY THE WHOOPING-COUGH IMMUNISATION COMMITTEE, MEDICAL RESEARCH COUNCIL

In view of the conflicting reports on the efficacy of pertussis vaccine in whooping-cough prophylaxis, the Medical Research Council was asked by the Ministry of Health to investigate the problem and report on the value of prophylactic immunisation against whooping-cough of children in England and Wales.

As part of the investigation, the Whooping-Cough Immunisation Committee organised a series of controlled field trials in which the experience of children inoculated with pertussis vaccine could be compared with that of control children. The results of some of the early trials have already been published.[1] The evidence obtained suggested that the pertussis vaccine used in these trials was of no value in whooping-cough prophylaxis.

Further large-scale trials have now been carried out in collaboration with the medical officers of health of Oxford, Manchester, Tottenham, Wembley, Edmonton, Leeds, and West Ham, using a number of different vaccines of both British and American origin.

METHOD

Each trial was planned in a similar manner. Children, mostly between the ages of 6 and 18 months, whose parents agreed that they should take part, were divided by the method of random sampling into two groups. The children in one group—the test group—were inoculated with the pertussis vaccine under trial, while those in the other group—the control group—were inoculated with an "anti-catarrhal" vaccine containing no *Hæmophilus pertussis*. After inoculation the children in both groups were kept under close observation for at least two years, by monthly home visits made by specially appointed nurse-visitors. Those children who came into known contact with whooping-cough or who developed symptoms which might be those of early whooping-cough received special visits in order that a bacteriological diagnosis might be made. Since it was essential that observers should not be influenced in their clinical assessment of the disease, efforts were made to ensure that neither the doctor, the nurse-visitor, nor the parents should know whether the child under observation was in the test or the control group.

RESULTS

Seven of the early trials, comprising a total of 4691 test and control children, have now been in progress for over two years, and from a preliminary analysis of the results the following general conclusions may be drawn:

1. In each trial the random allocation to test and control produced two equivalent groups of children, comparable in age, sex, duration of breast-feeding, size of family, and incidence of infections other than whooping-cough.

2. In six of the trials the incidence and severity of whooping-cough in the test groups were appreciably less than in the control groups. In the seventh trial the results in the test group were only slightly more favourable.

3. There was considerable variation in the prophylactic potency of vaccines from different sources, and there was probably also some variation in the potency of different batches of vaccine from the same source.

4. One particular type of vaccine, not at present readily available, was found to give decidedly better protection against the disease than any of the others tested.

FURTHER INVESTIGATIONS

The reason for variations in the prophyla
of these vaccines is not clear, nor is there
a conclusive laboratory method of assay b
property of a vaccine can be accurately asse
investigation is in progress in which the
value in children of a number of different vac
compared with their immunising properties
laboratory tests. With this aim in view,
already been begun in Manchester, Oxf
Poole, Walthamstow, and Leyton.

No investigation has so far been made of
combined pertussis-diphtheria prophylactic
considered desirable to avoid the inclusion
that might complicate the issue and to do
might possibly harm the diphtheria imm
paign at a stage when the true value of
immunisation was unknown.

This preliminary statement has been
account of the interest shown by health auth

used to spray the vaccinated area during t
period it reduces the yield of virus.

USE OF PHENOL

Phenol has been used since 1941 as a routi
at Elstree to obtain the rapid "purification
lymph, and it was also used by the Govern
Establishment from about the same dat
ceased production. At no time has the
indication that vaccine lymph issued with
centration of about 0·4% phenol deteri
rapidly than similar material *without this*

re any evidence that treatment of the crude lp with 1% phenol causes material destruction s.

1941, I believe, the Government Lymph nent had relied on the slow destruction of ting organisms by storage with glycerol and es. At Elstree we had for many years treated s of crude pulp with a stream of warm sterilised ed with chloroform vapour. This method was out involved two or three exposures of an to the vapour on successive days and caused reduction of viral potency; further, the m solution had to be "blown off" by a sterile air until a negative isocyanide test ned before the lymph could be glycerinated, and issued. The whole process, including nimals for potency, took about three weeks date of trituration of the crude pulp. During nge of information on methods with the nt Lymph Establishment in 1939, Lieut.- . D. H. Stevenson, then director, informed me had obtained encouraging preliminary results nol; we confirmed their results and by 1941 ed the method described below as a routine .

METHOD

uitable grinding machine x grammes of crude ulp is triturated with $2x$ ml. of 1% phenol in tilled water. The resulting mixture is incubated for 48 hours, and the bacterial examinations by the Therapeutic Substances Regulations are de. During this examination the vaccinial is stored at ± 4°C; it should not be stored C before the glycerol is added, since freezing occulation of the suspended matter. If the terial-count is higher than is desirable, or if gnisable non-sporing pathogens are still present, erial is returned to the 22°C incubator for a 24 hours, which is almost invariably sufficient ce a satisfactory result.

l at a concentration of 1% does not destroy poring organisms or anaerobes such as *Cl. tetani.* ious colonies or organisms of this type are seen re they must be individually examined, and ence of *B. anthracis* and *Cl. tetani* excluded by l tests. On the other hand, phenol destroys olytic streptococci and *Bact. coli*; staphylo- e destroyed more slowly. The Therapeutic ces Regulations now in force permit the issue ine lymph containing not more than 20,000 as per ml. after the exclusion of recognisable ns; at Elstree no lymph is passed that contains an 5000 organisms per ml., and indeed, most contain considerably less than 1000. Moreover, storage before issue there is always a further tial destruction of organisms.

the bacteriological examination is satisfactory, of glycerol is added to the pulp-phenol mixture; e final concentration of phenol is about 0·4%. the lymph is passed through a sterilised wire-mesh gauge 32) with aseptic precautions before it is in bulk below −10°C.

cy tests are carried out by scarification on the back of a white-skinned rabbit; twofold dilutions : 1000 to 1 : 16,000 are tested, and it is usual in confluent or semiconfluent lesions up to and g the higher dilution. Two dilutions of a labora- andard lymph of known potency are included very batch of tests. These potency tests are d at least once after the lymph is dispensed pillary tubes or other containers for issue. The ication" and bacteriological and potency tests necessary, be done in fourteen days.

SUMMARY

The routine use of phenol to obtain the rapid reduction of the bacterial contamination of vaccine lymph is described.

The procedure is extremely simple, and lymph so treated can be issued for vaccination a fortnight from the date of trituration of the crude vaccine pulp.

The quarternary ammonium detergent roccal, used either as a spray on the vaccinated area or in the treatment of the ground vaccine pulp, acts as a bacteriostatic rather than a bactericidal agent. It is therefore less suitable than phenol.

Note.—Since submitting this note for publication I have learnt that Gins (1924) and Lehmann (1937) recommended the use of phenol in the purification of vaccine lymph, and that Stevenson and Butler (1939) stated that 0·5% phenol could be used to prevent accidental contamination of vaccinia cultivated in the embryonated egg. It is nevertheless still true that the use of phenol in the routine preparation of vaccine lymph is not generally known.

A STATE PRACTICE IN SWEDISH LAPLAND

A. E. BERYL HARDING
D.M. Oxfd, M.R.C.P.

MEDICAL practice in Swedish Lapland has many features which contrast strongly with practice in most parts of England. Yet the general similarity of plan makes the contrasting details worth studying.

Sweden is divided into 500 medical districts, under the supervision of 24 regional doctors. Each of these districts, most of which have a population of about 5000, is in the charge of a State doctor. In most areas there are also private practitioners, but in remote places where the population is widely scattered and difficult of access, few private doctors are to be found; in Vilhelmina, the village in Swedish Lapland where I spent a fascinating week, there are none.

The organisation of a State practice is as follows. Doctors receive their salaries from the State. Their houses are provided by the community, the building costs being paid partly by government grant and partly from local rates. A small rent is charged for the part of the house used solely for personal purposes. The house in which I stayed, built in 1946–47, has, for professional purposes, a separate entrance leading to a small waiting lobby, off which is the nurse's room, where patients' names and particulars are taken. Beyond is the doctor's room with a small darkroom leading out of it, and a good-sized examination room excellently equipped for minor surgery. The writing-table, chairs, and other furniture are provided by the community; but couch, instruments, and all medical equipment are the doctor's property. The private accommodation consists of 2 living-rooms, a sizeable hall and landing leading on to a big balcony, and 4 bedrooms with labour-saving devices.

Two State doctors have charge of the district of Vilhelmina; each is responsible for an area of about

3800 sq. km. A woman doctor has charge of the wild, scattered, northern part, while a man takes care of the southern which includes the village of Vilhelmina; since his area is the more compact he is more accessible and so has charge of the hospital. When one of these two is away, the other cares for everyone in both districts and in the hospital. Patients from both areas can consult either doctor, and they do so freely; but owing to the immense distances neither doctor visits outside his or her area.

PAYMENTS

Doctors are paid a fixed annual salary, which varies inversely with the population of the district, because each patient pays a fee every time he visits either the outpatient department or the doctor's surgery; there are no booked accounts. The State fixes an upper and lower limit of fees, and the doctor is left to decide the amount which shall be paid within these limits. When patients are unable to afford a fee the doctor is paid by the community, or by the sick club if the patient is insured.

Patients pay for all drugs, which are obtained on prescription from the surgery or from the outpatient department; doctors do no dispensing. To patients in poor circumstances insulin and liver extract are issued free. Liquid paraffin, aspirin, and so on need no prescription and can be bought as desired. Prescriptions for iron, and those containing less than 15 mg. of barbiturate per dose can be used repeatedly by patients at their own discretion for six months after issue; thereafter a fresh prescription must be obtained. All other prescriptions can be marked "to be repeated once, twice, or thrice." The government exerts some control over the price of drugs and the composition of proprietary preparations. Inpatients receive all drugs and treatment free, but normally pay a small fee for board and lodging; when this is beyond the patient's means it is paid by the community. In the small district hospitals there are no private rooms. Anyone needing penicillin is almost invariably admitted since in this widely scattered district daily visits by nurse or doctor are out of the question.

The hospital at Vilhelmina is a well-equipped modern building planned for 18 general and 6 maternity cases, with some extra rooms reserved for emergencies or infectious cases. During the winter these extra rooms are brought into general use, and extra beds are put up in the wards, the number of patients often rising to as many as 30. An X-ray plant is operated by the district doctors, but cases needing elaborate technique—for example, gastro-intestinal investigations—have to be sent to Umea, 250 km. away. This can be reached by train; but some patients are sent by car, the cost being borne by the sick club or by the community if the patient is badly off and not covered by insurance. A simple outpatient department is equipped for general work and for such specialties as ear, nose and throat, and eye work, all of which are undertaken by the district doctors. Both doctors do all the operations for the district; anæsthetics are given by the nurses. Only cases needing specialised team-work are sent to Umea; serious emergencies are transported free by military plane.

A certain amount of emergency dental work is done by both doctors, but a new dental clinic is shortly to be opened and a resident dental surgeon has already been appointed. In this clinic there will also be accommodation for maternity and child-welfare work, which is now done at the doctors' surgeries. A tuberculosis dispensary serving several districts is under the care of a tuberculosis officer, who is responsible for organising sanatorium treatment when necessary. When he is on holiday artificial pneumothoraces are done by the State doctors at the district hospital.

NURSING

Visits are not paid to anything like the sa
as in England; after the first visit, much adv
by telephone. Visits may involve very
journeys, culminating as often as not in
through the forests or over lonely mountai

BRITISH ASSOCIATION

ADOLESCENT NUTRITION

opening session of the physiology section of
h Association for the Advancement of Science,
stle-on-Tyne last week, Prof. R. A. PETERS,
sident of the section, observed that much had
ten and said about adult nutrition, but very
ut adolescent nutrition.

. C. SPENCE said that while physiologists had
much, the practical application of their work
ed smaller than they had hoped. Nevertheless
he physiological advances had been assimilated,
result the nation had been fed infinitely better
te war than in that of 1914–18. Perhaps this
e evident in a large industrial city like New-
an in other places which had not suffered so
etween the wars.

s and infant-mortality were good indicators
ss. In Newcastle the infant-mortality, which was
00 in 1927, had fallen to 38 per 1000 in 1948.
rickets—a still more delicate indicator—was
a severe form in 5% and in a slight form in 16%,
it had virtually disappeared and the student
alk the wards without seeing a single case.
urrounding villages there was no difficulty in

d pasture.

sor Spence decried "the tyranny of the norm,"
ved that the onset of adolescence or pubescence
cur at any age between $10^{1}/_{2}$ and $16^{1}/_{2}$, and that
reflected in the enormous variations in the diet
tage. At 16 a boy or girl might still be a child,
maturity-age was preferable to the chronological
orking out dietetic needs. Children in this age-
ere, judged by mortality-rates, peculiarly liable
culosis—girls at first more than boys, though
death-rate among boys overtook that of girls.
adolescents attacked by xerophthalmia, though

until 11 years and thereafter in houses of fifty.
ding, which had always been central, had greatly
ed. Boys were weighed at the beginning, middle,
l of term. Quite often it was found that those in
ular house were not up to the average; and this
be traced to an unjudicious captain's putting his
undue physical strain. Yet the over-all picture was that of greatly increased height and weight. This increase must be due to some factor in the school régime, and he believed that this was dietetics. At one time the consumption of bread was 19 oz. per day and now it was down to 10 oz. Dr. G. E. Friend had been responsible for increasing the milk allocation from 7–10 oz. a day before the 1914–18 war to about 1 pint a day between the wars and during the late war. The boys had not suffered through the loss of fresh meat, which had to some extent been made good by corned beef, tinned meat, and fish.

During a month's survey of one house of fifty boys, he had found that they supplemented their diet, on average, to the extent of 250–300 calories—mostly in the form of carbohydrates. Like Professor Spence, he emphasised that a hungry boy would not necessarily eat anything put before him: potatoes especially were often refused, and the refusal of a particular dish often spread more quickly than an epidemic. The schoolboy must be understood if his needs were to be satisfied.

Dr. R. PASSMORE, speaking of his experience among undergraduates at Edinburgh, said that some of the senior members of the university were complacent, using the argument that what had been good enough for them was good enough today. The mid-term holiday was still called "meal Monday," and some undergraduates still celebrated it by returning to the croft to bring back their sack of oatmeal. Probably they needed it, for their only extra allowance was $^{1}/_{3}$ oz. of national milk cocoa a day. Yet a considerable proportion of undergraduates were still growing.

A dietary survey had shown that some undergraduates were eating little more than 2000 calories, whereas others were eating up to 4500; and there was a good deal of bartering of rations, particularly cheese. He wondered whether the apparently greedy eaters needed this extra compared with the small eaters, or, as he put it, whether some individuals could do more miles to the gallon than others.

Statistics showed that undergraduates ran an increased risk of tuberculosis. The primary cause of bad feeding was ignorance, supported by national tradition; and medical students were often no more enlightened than others. Of the students, 10% had less than 3 oz. of fruit and fresh vegetables daily. The landlady, he had found, was often more efficient than the mother; and this was almost invariably so when the student came from a broken home.

Dr. Passmore ended by speaking in support of a resolution by university medical officers, that every university should provide an adequate midday meal for non-residents.

HEALTH HAZARDS

Dr. R. E. SMITH, medical officer of Rugby School, discussed the stresses and strains of life, believing that they could be withstood more easily by the well-nourished child. The boys at his school were better nourished than the average in the community. Early-morning school, which put an unnecessary strain on the adolescent boy, was abolished in 1935. He quoted the incidence of fractures at Christ's Hospital and at Rugby and showed that in the years before the war fractures were slightly more common than during the war.

Certain diseases, particularly measles and whooping-cough, had a completely different symptomology in the well-nourished child. The principal difference was the almost complete absence of catarrhal symptoms; yet in measles the temperature chart was often identical with that for the child with catarrh, who might later contract complications such as otitis media, bronchitis, and bronchopneumonia. He also quoted figures showing that the bowel which had not been insulted regularly with aperients, laxatives, or purgatives threw off infection, particularly Sonne dysentery, in a surprisingly rapid way. The skin, if healthily sunburnt and kept in good condition, was able to tackle chickenpox and even measles more satisfactorily; and the eyes of a well-nourished child did not readily develop squints or an increase of refractive error. Moderation in eating was necessary lest acidosis and acne should appear. While acknowledging the experimental work indicating that the healthy monkey was more prone to infantile paralysis than one fed with insufficient vitamin B, he believed that the real factor involved was the amount of exertion.

FIRST INTERNATIONAL CONGRESS OF BIOCHEMISTRY

The first International Congress of Biochemistry, held in Cambridge from Aug. 19 to 25, was attended by over 1700 members from 42 different countries. In his opening address, Prof. A. C. Chibnall, F.R.S., the president, while looking to the future, laid an emphasis on the past most salutary for workers in a young science surging forward under the drive of new conceptions and techniques. The members of the congress were welcomed on behalf of the Government by Viscount Addison, Lord Privy Seal, and on behalf of the university by the Vice-Chancellor.

The congress, which was initiated by the Biochemical Society, met a need which had been felt for some while. Indeed, eight congresses had previously been organised by the Société de Chimie biologique, and to this body the president expressed the appreciation of all biochemists. The occasion was singularly appropriate for paying tribute to the memory of Gowland Hopkins. This beloved and revered man founded the Cambridge school of biochemists, and through his own work and that of his collaborators and pupils strongly influenced the development of biochemistry throughout the world. All three speakers in the opening session spoke of his work and personality, and a copy of a commemoration volume[1] containing his autobiography, selections of his writings, and appreciations of his character and influence, was given to each member of the congress.

On Aug. 20, the university marked the occasion by conferring the honorary degree of doctor of science on Lord Addison, Sir Charles Harington, Prof. C. F. Cori (U.S.A.), Prof. K. Linderstrøm-Lang (Denmark), Prof. A. W. K. Tiselius (Sweden), and Prof. J. Tréfouël (France). During the week, congress lectures were given by Professor Cori on Influence of Hormones on Enzymatic Reactions, by Prof. M. Florkin (Belgium) on Biochemical Aspects of Some Biological Concepts and by Sir Robert Robinson, F.R.S., on Tryptophan and its Structural Relatives.

THE SECTIONS

The communications were given *in twelve sections*, and their names show the wide range of subjects covered: I, animal nutrition and general metabolism; II, microbiological chemistry; III, enzymes and tissue metabolism; IV, proteins; V, clinical biochemistry; VI, structure and synthesis of biologically important substances; VII, cytochemistry; VIII, biological pigments—oxygen carriers and oxidising catalysts; IX, hormones and steroids; X, chemotherapy and immunochemistry; XI, plant biochemistry; and XII, industrial fermentations. In all, over 500 communications were presented to the congress, of which the following had special medical interest.

HEMS described a new synthesis of natural ine and J. LEGGETT BAILEY a new simple s of peptides. O. KAMM (U.S.A.) gave an account tructure and synthesis of the antibiotic chloro- , and of the purification and properties of the etic hormone of the posterior pituitary.

VII

were spirited sessions on mitotic poisons, tion of cell constituents, nucleic acids and roteins, enzymes and nucleic acid, lipids, and mical methods. J. S. MITCHELL reported clini- ls of large doses of tetra-sodium 2-methyl-1 : hohydroquinone diphosphate, mainly in con- ı with palliative X-ray therapy. The drug a small but useful improvement in the results atter in some cases of advanced cancer, a small in survival-time in inoperable carcinoma of the ıs, and retrogession of tumour cells in certain f adenocarcinoma. P. MANDEL and colleagues) stated that during protein starvation there was loss of ribonucleic acid in liver and muscle whereas oxyribonucleic acid was unaffected. Others ed the constancy of the latter in the cell. NTRENNE (Belgium) considered that cytoplasmic s are not divisible into large granules and micro- but form a continuous gradation in size. The t contain most ribonucleic acid, the largest the enzyme activities.

-VIII

e were valuable discussions on the structure of lobin, hæm-containing enzymes, cytochromes, and tabolism of porphyrins and bile pigments. C. G. ERG and C. B. LAURELL (Sweden) have isolated copper-containing protein, " caeruloplasmin," lood-serum. G. WALD (U.S.A.) described new ments in the biochemistry of rod vision ; sin is bleached by light to give retinene$_1$ (vitamin hyde) ; the latter is then reduced to vitamin A$_1$ enzyme retinene reductase, with reduced cozymase ızyme.

IX

. SOMERVILLE and G. F. MARRIAN described what parently a priming effect of progesterone on nediol production in postmenopausal women. TTSTEIN and C. MEYSTRE (Switzerland) reported 11-dehydro-progesterone has three times the tational activity of progesterone. P. M. COTES, ID, and F. G. YOUNG have found that pure growth hormone is diabetogenic in adult cats; they emphasised species and strain differences. S. BERGSTROM (Sweden) has isolated *l*-noradrenaline from adrenals. R. PITT-RIVERS gave a masterly review of antithyroid substances. C. H. LI (U.S.A.) has found that peptide fragments, containing on the average 7 amino-acid residues, obtained by hydrolysis of adrenocorticotrophic hormone, are more active than the hormone itself.

Section X

In a session on drugs and enzymes in chemotherapy B. A. FRY stated that the bactericidal triphenylmethane dyes inhibit glutamine synthesis in extracts of staphylococci, and E. D. WILLS that suramin inhibits several enzymes. E. CRUZ-COKE and M. PLAZA DE LOS REYES (Chile) found that tricresyl phosphate, which has anti-vitamin-E action, retards or arrests the growth of sarcoma implants in rats. In another session the question of the relative importance of the carbohydrate and nitrogenous parts of antigens was discussed and the need for new techniques of purification became clear. In a meeting on drug-resistance P. D'ARCY HART stressed the danger of development of streptomycin-resistant human tubercle organisms, and suggested the administration with streptomycin of a drug such as *p*-aminosalicylic acid which does not readily give rise to resistant bacteria. It was mentioned that M. MACHEBOEUF (France) has made organisms resistant by contact with extracts of a resistant strain. P. SCHAEFFER (France) described a type of resistance to streptomycin in which the latter becomes a growth factor for the resistant strain. A. BISHOP has produced resistant malaria parasites by subcurative doses of proguanil or sulphadiazine in infected birds. In a meeting on immunology P. GRABAR (France) urged that antibody production should not be regarded as a specific protective mechanism against infection but as an example of a physiological process in which globulins act as carriers for metabolic products. M. HEIDELBERGER (U.S.A.) suggested that carbohydrate antigens, unlike protein antigens, persist in the body for a long time. No theory of the antibody-antigen reaction received the support of all present.

CONCLUSIONS

All agreed that the congress was a success. The glorious weather, the lovely setting of university, college, and town will leave a lasting impression on those who took part. The value of a congress does not lie solely in its scientific sessions ; and in little informal gatherings and parties, as well as at the receptions and dinners, biochemists from many lands met to exchange ideas, to resolve differences of opinion, and to strengthen old friendships and initiate new. Speaker after speaker at the closing session emphasised in happy phrase the easy coöperation and agreement between members from different countries ; and one feels it was not only the common aim, but also appreciation of a deeper significance, which drew all together in amity.

This readiness to agree is exemplified by the working of an ad hoc international committee which met during the congress under the chairmanship of Sir CHARLES HARINGTON, F.R.S. This committee put forward the following resolutions :

1. That the invitation of the Société de Chimie biologique for the holding of the next international congress of biochemistry in Paris in 1952 be accepted with gratitude.

2. That an international committee for biochemistry be now set up and that it have the following composition (here followed the names of Sir Charles Harington, chairman, and of 20 representatives from all parts of the world) and that this committee be empowered to coöpt additional members from other countries as may be desirable.

3. That this committee be instructed to approach the International Council of Scientific Unions with a request for recognition as the international body representative o

biochemistry, with a view to the formal constitution of an International Union of Biochemistry, as soon as possible.

These resolutions were unanimously adopted by the congress at the closing session. So the congress ended on a note of international collaboration achieved, with a promise of even greater coöperation in the future. Professor Chibnall is retiring from the chair of biochemistry at Cambridge, and it must give him great pleasure that his tenure should have ended with his presidency of this happy and successful gathering. The congress has emphasised the dignity and independence of biochemistry as a discipline. Once merely on the borderlines between older sciences, it now forms a focus at which biochemists and workers in other sciences, old and new, meet for the solution of problems of common interest and the promotion of the health and happiness of mankind.

Public Health

REORGANISATION OF THE HEALTH SERVICES IN THE BRITISH ZONE OF GERMANY

WILFRID G. HARDING
M.R.C.S., D.P.H.
HON. LIEUT.-COLONEL, R.A.M.C.; LATE PUBLIC-HEALTH OFFICER, RUHR DISTRICT, BRITISH ZONE

AMONG the many tasks in Germany which faced the public-health branch of Military Government, and later of the Control Commission, reorganisation of the health services was probably the most urgent, and the most difficult. The condition of country and people made an efficient health administration more essential than ever, and direct administration by the Allied staff—a small group of public-health officers most of whom did not speak German—was impossible for any length of time.

UNDER THE NAZIS

When the National Socialist government came into power in 1933, they decided to retain most of the civil servants. The civil service had enjoyed for many generations a unique reputation in the country, and the new government realised that the large conservative element within the service could be relied on to support the nationalistic tendencies of the new régime, while its efficiency would suffer severely if there were many changes of staff. However, all active supporters of other political parties, as well as all Jews and most non-Aryans, were dismissed, and those suspected to be not wholly in favour of National Socialism were transferred to posts of little responsibility, and their promotion blocked. To replace those dismissed, loyal Nazis were appointed, often regardless of the fact that they did not possess the necessary qualifications. The service was to be recruited in future only from pro-Nazis, and arrangements were made for the intimidation, indoctrination, supervision, and control of non-Nazis retained in it.

For about a hundred years the public-health services had been run directly by the central government. Rumsey (1856) describes their organisation very much as we found it existing in 1945.

The authority deciding on policy and appointments was the ministry of home affairs of the Land concerned. In Prussia the Land ministries were amalgamated with those of the Reich in 1933, and the public-health service was thenceforward the responsibility of the Reichministerium des Innern. It was administered through provincial (Provinz) and regional district (Regierungsbezirk) headquarters by medical officers who were responsible for the local public-health organisation, for the inspection of hospital, sanitary, and pharmaceutical services, and for the professional nursing examinations.

The local administrative unit was and
the Kreis, of which there are two types—the
(county borough with population from 50,000
and the Landkreis (county or rural district wi
tion varying from 20,000 to 250,000). The
medical officer of health at these levels is the
who is the head of the local public-health
(Gesundheitsamt). From 1933 these appoin
made by the minister of home affairs, and the
was responsible to him through the interm
described above.

The Nazi party also ran its own health se
function it was to ensure that the people's
safeguarded and promoted according to part
and the best interests of the State. This o
was entirely separate from the State public-heal
and at Kreis and higher levels there were s
health offices with a hierarchy of "health
(Gesundheitsführer).

Thus the local public-health service was
under strict central control; there was also
check on its doctrinaire reliability at all leve

.

A special complication, moreover, affected the medical profession. In the same way in which the British doctor is given a commission as soon as he joins the Forces, many a German doctor had been given relatively high rank in the party organisation by virtue of his appointment as medical officer to one of its formations. This was rarely taken into consideration by the Allied security authorities who had been given definite instructions on the valuation of membership and rank, and whose discretionary powers were strictly limited. Thus one could find in the internment camps as large a proportion as 1 doctor to 50 other inmates—a rate about fifteen times higher than that of doctors in the general population. Similarly a large proportion of the medical profession had held party rank which now put them into the compulsory removal category. No one seriously believed that there had been more fanatic Nazis among the doctors than in any other profession, but no official recognition was given to their special position. It was ruled, it is true, that the general practitioner was not to be considered to hold public office and was therefore not to be subject to denazification procedure, but hospital staffs. and of course medical administrators, were to be denazified under the general regulations.

A further complication was the fact that almost all public-health officials had, in the course of their duties, been concerned in eugenic sterilisation, according to Nazi legislation. Public Health Branch ruled after consultation with British legal experts that if such activities had been strictly within the laws then in force they were not to be considered as disqualifying Nazi activities, but often indignation of the local population caused difficulty, and it was almost impossible to judge in retrospect the merits of any particular case.

Finally, difficulty arose out of the antimilitaristic clauses of the denazification regulations, which denied public office to all who had held regular commissions in the Fighting Services, as well as to temporary officers of field and higher rank. This paradoxically affected many—among them a number of hygienists—who in order to avoid membership of the party had elected as the only possible alternative to join the Wehrmacht, which, especially in the earlier years of the new rule, was considered relatively isolated from Nazi influence.

The British public-health officer charged with the re-establishment of an efficient service was thus faced with an insoluble problem. Most of the senior members of the old service had been removed to camps, and practically all other members of public-health staffs were ineligible according to the denazification rules. Our only chance was to invoke the risks which the prolonged disruption of the health services would cause—risks which would affect occupiers no less than occupied. On those grounds it was often possible by local compromise to retain and re-employ medical officers who to us appeared relatively harmless politically. But this solution was not generally recognised and depended entirely on the good will of the responsible public-safety officer. Moreover it was invariably agreed to as provisional only, and thus perpetuated a feeling of insecurity in the holder of the post, who was often subjected to open attack by fellow Germans, and even more often to whispering campaigns and denunciation.

If competent men were disqualified on their party records, so equally had some incompetent men been put into office on the grounds of their past record of persecution by the Nazis. Such men usually had considerable political backing and it would have been almost impossible for the Occupying Power to cause the removal of a proved anti-Nazi, however incompetent. It also became regrettably obvious that religious and political factions were trying to sponsor appointments in the public services, and, despite the object lesson they had been given during the preceding twelve years, they professed not to understand the Occupying Power's rejection of a staffing policy conducted according to religious and political allegiances.

STAFFING THE POST-WAR SERVICE

Nazi policy and our denazification procedure resulted in a shortage of staff, and in a regrettably mediocre standard of those who were left to hold office. Of those who had stood out in pre-Nazi days, the younger men had often been liquidated or had gone abroad, and only a few old men remained, hardly fit to adapt themselves, after many years in retirement, to the tremendous post-war tasks. Most of the efficient men of the Nazi era were now unemployable. Thus, at a time when initiative and drive were essential, the administration was largely in the hands of men who were too old, or who were second-raters, most of them constantly worried that their conditional employment might yet be terminated. At a time when decisions were required on fresh problems arising out of the post-war situation, these officials appeared tied down by obsolete regulations and laws. Discretionary power when given to them was rarely used; our direct orders were welcomed. Typical of this attitude was a remark made by the German chief medical officer of my own regional district, quoted by Count Bernadotte (1949). He had had 30 years' service in the German public-health administration; yet, when I told him that we were abandoning direct control and that he would now be responsible for his own department, he replied quite shocked: "But Herr Major, it is you who must command."

The same attitude prevented the recognition and out-of-turn promotion of young men of outstanding ability. In one instance I insisted on the transfer of a brilliant 36-year-old Amtsarzt from an unimportant rural district to a much more difficult district in the Ruhr. His political record was exceptionally clean; in fact he must have schemed with considerable ingenuity how to avoid joining the party. His record of service was excellent. Yet his superiors, including the head of the German regional administration did everything to dissuade me from my project, for one reason only—namely that every previous holder of his new post had been over 55 years old when appointed to it.

The German chief medical officers of each province, and later of each Land, constituted an advisory committee which met once a month at zonal public-health headquarters. The preparation of legislation to replace the German public-health law of 1935 was one of their most important tasks, for after the formation of the autonomous Länder health legislation was to be delegated to each Land, and it was therefore essential to agree on uniformity in all essentials before these laws were enacted. Similar committees dealt with nursing and pharmaceutical questions.

One of the early results of their discussions was the resumption of postgraduate public-health teaching. The two hygiene academies in Hamburg and Düsseldorf began 12-month courses in 1946, each for 35 students, and in view of the shortage of hygienists selected candidates with practical experience were also admitted to intensive 3-month courses.

RETURN OF RESPONSIBILITY TO THE GERMAN AUTHORITIES

In January, 1947, the new Länder were constituted, and direct control of public health reverted to the Germans, though a small British staff remained for liaison and guidance and the regional commissioner retained rarely exercised powers of veto. We were, however, never able to induce the German officials to regard us as advisers, and they still expected, and clearly preferred, to receive direct orders.

In each of the Länder a ministry of social we established which took over the public-health welfare services. Under the minister a permanent secretary is responsible for both and the public-health division is headed by chief medical officer, assisted by departmental officers and the regional district medical officer act as district inspectors for the new ministry.

Simultaneously the local public-health services part of a new local government set-up fashioned on the English pattern. The med of health (Amtsarzt) ceased to be responsible the central government health organisation. the local council, he was responsible to it all new appointments required confirmation ministry.

It might be expected that M.O.H.s would their release from central control and would greater freedom of action, but exactly the occurred. Military Government was inunda protests, and in the end a formal request wa the society of German public-health officials to public-health services under central control. Th they gave was fear that M.O.H.s would from now be under the direction of their town clerks dragged into party politics. Reminders that arrangement was operating satisfactorily in were commonly answered with a shrug of the and the argument that England had a few h start in the running of a democratic system.

CONCLUSIONS

It is, I think, important to all who are int the post-war development of German public recognise the difficulties under which the new laboured during the first years of its existence have therefore dealt with them in some detail. also be stated, in all fairness, that the German who were in office after the war almost worked with extreme conscientiousness in the many practical difficulties, such as the loss of their equipment, and records, the lack of transport, of stationery. Apart from the feeling of tenure almost all of them had their own serious problems—the loss of their living accommodat the constant worry of how to feed their families.

The new central and local health organisat been in existence for about eighteen months the zone, too soon to express a final judgment it was obvious that it would require a long time itself to the change. Here this country can give able help, not so much by direct interference and —that would be against our policy of intro democracy into the zone—as by an extensive pro of exchange visits. A promising start was year under the auspices of the Foreign Office Ministry of Health, and it was most satisfa observe the reaction of university hygienists, medical officers, and medical officers of health their visits to this country. It is to be hoped scheme will be continued and extended, and wil full support on this side of the Channel.

My thanks are due to Brigadier W. Strelley Mar public-health adviser to the Control Commission for (British Element), for permission to publish this also wish to record my profound gratitude to Maj J. G. Gill, C.B.E., D.S.O., for his patient guidance the two years in which I served under him.

Q Fever in London

11. 12, and 13 three members of the pathological one nurse at a London hospital fell ill with ared to be atypical pneumonia. All recovered, uent investigation has shown that all now have ly high agglutinations against *Rickettsia* this rickettsia has also been recovered from le of blood. The usual incubation-period r (10–24 days) has now expired and there is r spread of the disease in the hospital. The infection is being investigated.

believed to be the first occasion on which has been recovered in this country. Stoker[1] ggestively high titres in atypical-pneumonia ut there has been no unequivocal serological evi- source of infection here. Q fever was first dis- l as a human disease in Queensland, Australia. and was thought to be tick-borne. Later out- slaughter-house workers in Chicago and in re attributed to inhalation of tick fæces or ner rickettsia-contaminated material. In he disease was recognised in Greece and the pennines; it has also been reported from d and Algeria.[2] In the U.S.A. endemic foci n identified in California. but the eastern was not involved until 1948. In some outbreaks e not been involved and the mechanism of mains uncertain.

nall outbreak in England. where there is no of endemicity. may be no more than an isolated on. but it calls for special vigilance. Early n of the disease and the correction of any ental factor likely to encourage spread may the establishment of endemicity. Thus it is that outbreaks of atypical pneumonia should ht to the notice of medical officers of health. for routine laboratory diagnosis are not avail- ospital laboratories. Serological studies will be en through the Virus Reference Laboratory at , London. in selected instances when special ents are made.

l Features.—Q fever is an acute febrile osely simulating virus pneumonia. It may re- fluenza. primary atypical pneumonia, psittacosis. r obscure fevers. The disease is characterised en onset. which can be dated; headaches ly retro-orbital): weakness; sweating; and l body aches. Often there is pleuritic pain and ometimes with bloodstained sputum, though ation is as a rule scanty. As in virus pneumonia. signs of pulmonary involvement are relatively mpared with the radiological findings. which rally speaking indistinguishable from primary pneumonia. The white-cell count is normal or h relative lymphocytosis. Fever is usually l persists from one to ten days or more: in ses it continues for three to six days. may be pronounced at the onset, and the fever very debilitating. Q fever is distinct from the kettsial diseases (epidemic typhus, scrub-typhus. Mountain spotted fever, rickettsial pox) by the cutaneous lesions. A fine vesicular eruption duration is seen in less than 10% of cases. The ix reaction is negative.

Poliomyelitis

week ended Aug. 27 notifications in England les numbered: poliomyelitis 258 (273), polio- itis 22 (22). Figures for the previous week are n parentheses.

ollowing counties reported multiple cases (polio- and polioencephalitis together): London 34 (35). e 3 (11), Cheshire 8 (6), Cornwall 5 (8), Derby evon 4 (9), Dorset 2 (1). Durham 3 (2), Essex Gloucester 15 (5). Hertford 6 (3). Kent 9 (6), er 33 (29). Lincs Lindsey 3 (3), Middlesex 17 (13), apton 4 (6), Northumberland 6 (7). Nottingham Somerset 7 (5), Southampton 16 (11). Stafford uffolk East 2 (0). Suffolk West 2 (3), Surrey 5 (7). East 4 (2). Sussex West 2 (3), Warwick 7 (4), e 3 (4), Yorks, East Riding 3 (1), Yorks. North (1), Yorks, West Riding 33 (50). Monmouth 2 (2). Of the 15 cases reported from Gloucestershire, 14 were in Bristol C.B.

For the first time in five weeks there has been a small fall in notifications. Thus the curve of incidence so far this year has been very similar to that in 1947, though at a much lower level. The figures of notifications for the corresponding week (week 34) of 1947 were: poliomyelitis 626. polioencephalitis 50.

Epidemic in India.—It is announced from W.H.O. headquarters at Geneva that a poliomyelitis emergency is developing in Bombay and other parts of India. Poliomyelitis is said never before to have reached epidemic proportions in India.

Canicola Fever in Bristol

At Shirehampton, Bristol. a husband and wife attended the Eye Hospital with cyclitis. Inquiry showed that each had had a febrile illness a few weeks previously. Canicola fever. in which eye symptoms often arise during convalescence. was suspected and has been confirmed by serological tests; and the community in which these patients live is being investigated. Clinical evidence suggests that there may have been some unrecognised cases in conjunction with infection in dogs: and it is understood that positive agglutination tests have been obtained in the sera of 5 of the dogs examined.

Dogs are very commonly infected with *Leptospira canicola*, and infection in man is being brought to light increasingly often. The disease normally runs a benign course. though one fatal case has been recorded.[1] In the early acute stages it sometimes gives rise to symptoms of meningitis, which may lead to confusion in diagnosis.

Medicine and the Law

A Chef's Cure for Tuberculosis

An ex-Viennese chef, living in Kensington, was fined £10 at West London police-court on Sept. 1 for having unlawfully advertised by circular and letter a substance known as 'T.35' for the treatment of tuberculosis. There was a further charge of selling T.35 in a package which did not bear a label showing its composition. There was evidence that the substance was found to be ground laurel berries, costing about 2s. per lb.

The prosecution stated that an inspector of the Pharmaceutical Society of Great Britain wrote to the man for particulars of his treatment. The accused, in reply, stated that T.35 had been used for the cure of tuberculosis in Germany for 27 years and that the cost of a quantity sufficient for the treatment of a case was £5. There was a stipulation that the treatment must be superintended by a doctor.

It would be interesting to know if any medical practitioners have been invited to superintend the treatment with the defendant's laurel berries. He told the inspector that he was only an agent for T.35 in Britain. He thought that he was not committing any offence, inasmuch as he had not inserted any advertisement in a newspaper.

In England Now

A Running Commentary by Peripatetic Correspondents

ON this, the fortieth anniversary of my first driving licence, I think I am entitled to look back with gentle satisfaction. My immunity from accident may be ascribed to Goddës grace, but I can at least claim to be a long-suffering driver.

Skill in driving varies from hour to hour. My two great enemies are fatigue and preoccupation, the latter including both the distracting influence of passengers and simple wool-gathering. In my experience a little alcohol tends to improve skill, as judged by the objective tests of more accurate parking and nicer judgment of distance ; but it is a very short step from this point to dangerous over-confidence. Alcohol in considerable quantities increases my sense of cleverness, but I fail dismally in the practical tests.

The autossytic diseases are mainly psychogenic. One of the commonest—cornucopia, or much-sounding-of-the-horn—is far more conspicuous abroad than in Britain. In Lisbon, for example, all drivers blare night and day as a matter of routine. They even bay the traffic lights on the Avenida. In the London area the disease is confined to speed obsessionists on the by-pass avenues, and to a few timid creatures at crossroads in the city. Unfortunately our police, despite the *Highway Code*, still keep up the fiction that sounding the horn is evidence of good driving.

A similar ailment—much-grinding-of-the-brakes—is one of the sequelæ of the speed mania. As a symptom it is prominent in drivers who do not own the vehicle they drive. I used to believe that the trouble was confined to mild little men who were repressed at home, but it has deeper roots and is usually evidence of selfish disregard of the elements of courtesy. It is much more difficult to present the symptoms and clinical features of the form of exhibitionism associated with the use of full headlights, even in the soft light of dusk. This disorder is more common on the Continent and in U.S.A., where it is encountered in an aggravated form. Unhappily the disease is beginning to assume epidemic proportions in the outer London area. I regard this sign of discourtesy as yet another mark of the general feeling of insecurity that pervades the world of today.

*

Subjective impressions are notoriously deceptive, and it is hard to describe the signs of good driving. I have been obliged to devise a few practical clinical tests of good and bad conduct on the road. The simplest method (and the safest on the highway) is to keep records of positive acts of courtesy or discourtesy by drivers of various types of vehicle. I have done this over many years, and the time has now come for me to present my results diffidently to my colleagues. Diffidently, I say, because I am acutely aware of the pitfalls in the method. In the first place, the records relate mostly to the outer circle of cities, especially Edinburgh, Glasgow, and London. Secondly, they bear no relation to the order of frequency of the vehicles on the road: acts, easily recognisable as courteous or discourteous, often spring up without warning in a particular situation, and then opportunities may spread like a minor epidemic. One act leads to another. Often days pass without matter for note, and suddenly, perhaps in a crowded period, a whole volume of incidents takes place.

One obvious difficulty in the scheme is to decide what acts ought to be counted with the angels or against them. After several false starts I accepted the following categories and stuck to them, trying to limit personal bias as far as possible. Among the courteous deeds listed were :

1. Going out of one's way, so to speak, to help the infirm by giving them abundant room to cross the road. But what a death-trap these marked crossings can be, when one driver tries to be considerate only to find that the fellow behind him ignores his signal and crashes into (or mercifully past) the trustful pedestrian! I have seen so many narrow escapes at marked crossings in outer London that I am positively terrified to signal on the woman with the pram, and pull up to let her cross.

2. Giving clear, unequivocal signals to pass when the way is clear, and correspondingly good warnings of traffic obstruction—in other words, trying to be helpfu who are behind.

3. Being kind to those who make a mistake, down, for example, to make a transgressor's Self-righteousness is one of the gravest psycholog of the road, and is often a cause of accidents easily have been prevented.

4. Making an effort to help a fellow-driver in situation. At some time or another we become a narrow street, and the exit seems for ever beyond We perspire. Suddenly a little courteous fellow-driver makes a gap wide enough for us to into the great highway. Some months ago I was Western Avenue in the great fog. By a mis entered the wrong track of a two-way road and st thin curses of the driver who had followed me my temper a huge truck came at me from the stopped a few inches from my nose. The driver down. "Son," he said, "You are offside; can I across ?"

*

It is not for me to linger over clinical des the disorders of motoring. This has already admirably, in the *Highway Code*. Neverthel pause for a moment to examine some of the feed these distorted growths. In the early motoring sheer aggressiveness was a ruling sometimes ponder sadly on the fact that man most amiable of my fellow creatures, on possession of a vehicle capable of dealing destruction, at once reveal instincts most violent. My uncle Malcolm, a sober Clapham, used to pilot his two-cylinder Renault the quiet lanes of Surrey, at peace with the the sound of a horn behind him instantly whole being : the car shot forward and dust from its heels, smothering the passers-by. He in fact, like a runaway horse, but his sole to keep ahead of the enemy.

One interesting feature of my observations important change has taken place since I be at the end of the first world war : my 10,000 the same answer as the original 1000. How word it ? I can't express acts of good or ill in the number of vehicles on the road, for such ac concertingly irregular. But I might be allowe ment as a percentage for each type of vehicle. In every 100 acts recorded so many were so many discourteous, for each kind of dri sum works out as follows :

Vehicle	*Courteous*	*D*
Heavy truck or lorry	90	
Ordinary private car	70	
Light van (including, alas, newspaper deliveries)	50	
Sports car	40	
Chauffeur-driven private car (vicarious speeding, &c.) ..	30	

I have excluded buses and taxis from the accoun because they are not common visitors to the out

Can we assess some of the reasons for these in behaviour ? Chauffeurs are not unkindly I believe they are often images of the men be who have a lower sense of responsibility than th driver. The driver of the sports model is usuall and he wants to show off to his girl. He is noisy and aggressive, and he persistently ignores Fundamentally, he thinks that driving is a form and treats the open road as if it were a track de his benefit. The driver of the light van is oppressed by a commercial desire for haste. Fo transport vehicle is a means to an end. He craftsman's interest in it, and I suspect that despises the little brute, especially when his (with a sad lack of taste) blazon its sides wit or—worse still—decorations. How would you drive an imitation pineapple ?

The driver of the heavy truck (bless his craftsman and a gentleman of the road. He take in the open highway for its own sake, for it is hi Furthermore, he has learned the great rule of take, of consideration for the weaker vessels th so easily be crushed beneath his weight.

ger," said Mrs. Brown, "is rather a vague en he didn't come down one morning I looked and he said he felt ill, so I called the doctor sed tonsillitis, put him on the usual tablets, fluid diet, and asked for a specimen. The he'd like a cup of weak milky tea, so I took im and also a bottle for the specimen. Next t up the tea was gone but he hadn't done bout the specimen, so I took one from the ent it up to the doctor. Half an hour later the telephone to say that he was sending an to take my lodger into hospital because he tis and what was the name and address of his ? Well, we sent the lodger off in the ambu- two days later he walked in quite well again. , I thought, for nephritis from what I'd heard ll, of course, what happened was that he had nst the tea after the first mouthful and poured to the jerry, so the specimen I sent up was men, don't you call it ?"

e take sugar in his tea ?" I asked. "No." Brown. "A good thing," I said. "He e had diabetes as well."

* * *

No sooner had the three doctors reached the deserted wayside station than they heard the incongruously loud horn of the "Empire Builder." Soon this massive transcontinental streamliner rounded the bend and its powerful searchlight, sweeping up the track, illuminated the silver birches and swamps which bordered the great Mississipi river. Two minutes later the orange-snouted diesel engine hurried beyond the bend of the station platform and brought its immaculate steel cars to rest. The grinning negro attendants, with shiny white teeth and spotless blue uniforms, immediately appeared in the foyers, directing the Australian to his sleeping-car, while the air-conditioned passengers looked down approvingly at the newcomer. Hastily he bade his friends farewell, climbed aboard, and smiled down at them. The long fleet of coaches gathered speed and rapidly faded out of sight, with the observation car gleaming to the last in the rays of the setting sun. At the Twin Cities it would turn due west, traversing a thousand miles of prairie and the mountain ranges of Glacier National Park; speedily it would take the visitor to Portland, Oregon, and so on to San Francisco, where a plane would take him home via Honolulu.

Silently the two doctors returned in the Oldsmobile towards the sleepy town of Winona, over the high single-span bridge which leads back to Minnesota. Beneath them lay forest-studded islands and white pleasure craft sparkling in the tranquil waters of the broad upper reaches. Behind them rose the colourful hills of Wisconsin. "He is a swell fellah," said the doctor from the Mayo Clinic to his companion. "You know, a visit from a guy like that does more for good international relations than an embassy full of diplomats."

* * *

I have just been browsing through my *List of Abbreviations used in Prescriptions*. It is, I am afraid, a sad reflection on the effete old days before the Act and we are doubtless due for a committee to effect a drastic revision. Before it is too late, may I plead for "*Deaur. pil.*—let the pills be gilded?" The shop steward, of course, will be certain that *deaur. pil.* was a prescription exclusively for the squire and his relations and will prefer our democratic medicine with plain pills for everyone. I like to think, though, that the real use of *deaur. pil.* was on Christmas Eve, when the successful practitioner could celebrate the occasion with a round of gilded pills for all his patients. Perhaps the committee might let it go into respectable retirement as a red silk motto over some Ministerial mantlepiece.

No such pleading must save "*Ne tr. s. num.*—do not deliver unless paid." What a ghastly indictment the cartoonists would make of this! Under the heading "Medicine in the Bourgeois State" one can see the doctor's apprentice, top-hatted and with blood-stained coat, leaning insolently against the door-post while he holds aloof the bottle of life-giving fluid and repeats relentlessly, "*Ne tr. s. num.*" to the expiring pauper. The committee will have to expunge it, but perhaps they might recommend the use of "*q.p.*—as much as you please" in its stead.

* * *

After a busy day spent in doing differential blood and bone-marrow counts, one finds it difficult to stop counting when working hours are over. Thus, though one has come to America to do hæmatological research, one tends to stray into other fields. For example, as one sits in the hospital cafeteria, the 'Nylon' uniforms worn by many American nurses make one's attention wander from the foodstuffs. The difference between the words translucent and transparent was carefully explained to us at school. These uniforms are transparent. So the differential counting can continue during the meal hours. Somehow the nylon uniforms to date have all ceased to be transparent at the waist level, but in the upper reaches there appear to be three possible types of garment visible beneath. The uppermost has two sets of straps; all differential counts so far have included one example of this piece of apparatus. On most days there is also worn what is technically known as a "slip," but on hot days this is replaced by a "half-slip," the intervening area being pink. It is possible to do white counts, pink counts, and, on one occasion, even a blue count on these garments. During really hot weather the true gentleman of course avoids the cafeteria.

Letters to the Editor

CLINICAL PATHOLOGY

Sir,—A recent leading article,[1] discussing the hæmatological diseases of infancy, called for more coöperation between the physician who specialises in hæmatology and the pædiatrician.

At the time it occurred to me that the phrase "physician who specialises in hæmatology" was either a needless circumlocution for clinical pathologist, or an attempt to provoke a reaction from the increasing number of pathologists who favour the development of a concept of clinical pathology as an approach to medicine distinct from that of the clinician on the one hand and the academic pathologist on the other. This article resulted in only one cheer—from Dr. A. Piney,[2] who applauded the inference that hæmatology was the province of the specialist physician.

Clearly you were not merely indulging in circumlocution, for you repeated your contention in unmistakable terms in a further leading article on Aug. 6 (p. 243): "The hæmatologist, on whom these surgeons rely, is not a clinical pathologist: he is a physician, a clinician who is capable of making his own assessment and if necessary a personal interpretation of the hæmatological data and material . . . in the light of the clinical picture as a whole."

This challenge was taken up by one of our foremost clinical pathologists, Dr. S. C. Dyke (Aug. 13, p. 303). Unfortunately Dr. Dyke took these words from the article—"a clinician who is capable of making his own assessment and if necessary a personal interpretation of the hæmatological data and material"—and suggested that this was a perfect definition of a clinical pathologist. No clinical pathologist will mistake Dr. Dyke's meaning, but as it stands does it not concede the argument? Is a definition of clinical pathologist to begin "a clinician who . . ." or "a pathologist who . . ."? For this is the whole substance of the debate.

So far no attempt has been made to formulate a succinct definition of clinical pathology. Those specialists who make a point of calling themselves clinical pathologists have a fairly clear idea of its content, its method, and its value. "Bringing the laboratory to the bedside" is a picturesque description, but not very enlightening or convincing to the sceptic or uninitiated.

The war and post-war years have seen great expansion in pathological services, exceeding that in any other branch of medicine. This expansion took place even though the number of trained pathologists was quite inadequate. It was impossible to provide each new laboratory centre with expert morbid anatomist, bacteriologist, hæmatologist, and biochemist, who formed the principal staff of the pathology departments in the teaching and larger municipal-hospital laboratories. At the same time, the demands on laboratory workers developed a new emphasis: chemotherapy, antibiotics, blood-transfusion, and epidemiological investigations called the laboratory-worker more often away from the laboratory bench to the ward.

Perhaps without being aware of it, the majority of pathologists in the Emergency Medical Service and the associated Emergency Public Health Laboratory Service found themselves practising clinical pathology, acting as consultants in those diseases where diagnosis and therapy depend largely on laboratory findings, and developing a new technique of coöperation between clinician and laboratory-worker. One manifestation of this new emphasis was the rapid increase in the membership of the Association of Clinical Pathologists.

At present the inadequacy in the supply of pathologists is being made good. The pattern lishments now being designed for pathology in the health service is once again a consultant of the special departments. This is undoubt good. But it would be a great loss if these were to abandon entirely the new approach to pathology which has received such impetus in years.

There is perhaps a real danger that one cerebrospinal fluid, for example, may be inv three separate departments, each unaware of the findings and all sublimely unaware of the pa for this reason that a clear definition of clinical is needed—to crystallise an outlook and pra has done as much as, and perhaps more than to raise the general level of medical practice country in recent years.

I put forward as a tentative definition: " pathology is the laboratory analysis of sym signs," and for the sake of completeness "and the laboratory control of therapy." definition brings the clinical pathologist straight wards and faces him with the needs of the p makes clear that his method is laboratory m leaves no room for misconception of him as an physician. Yet his work demands considerable training. An important point is the em laboratory method. It is difficult for the to appreciate fully that the interpretation of results is intimately associated with the t used to obtain them. And it is the acquisition techniques as his primary tools which distin pathologist from the physician. Herein lies the of the remarks in your leading articles.

If a specialist chooses to practise clinical pat yet call himself a physician, he of course ma there is no more ground for calling hæma province of the physician than there is for calling histology the province of the surgeon or bacte province of the medical officer of health.

The question is one of orientation. The p only gain when the clinical pathologist thinks of in terms of plasma-proteins; he can only lo physician fails to think in terms of malnutrit both think of œdema.

Does this ban laboratory methods to the ph By no means. The physician must have some in clinical pathology. But the physician who h looks down the microscope is in grave danger of sight of his patient.

PREVENTION OF BURNS AND SC

Sir,—May I let you know how the problems Dr. and Mrs. Colebrook in their article of July 30 to the textile chemist?

It is appalling to read of the loss of life and suffered by young children as a result of their catching fire. That little or nothing has been d prevent accidents of this type is dismaying, be very largely due to widespread ignorance of frequency. In this respect the article will do g

There is no easy solution to the problem of cotton, wool-cotton mixtures, or viscose rayon non-inflammable; if there had been, it would d have been adopted. The application of the large quantities of metallic salts necessary to cellulose fabrics non-inflammable is always acco by serious disadvantages; the most obvious of that the "handle" of the fabric is badly affected roughened and no longer has the kindly "feel" is one of the most widely appreciated charact textile materials.

---

[1] *Lancet*, 1949, i, 919.

[2] Piney, A. *Ibid*, p. 1023.

ỵ, the fire-proofing of textiles usually depends plication to the fabric of some chemical which, ted, will chemically "destroy" the fabric ignition temperature. Phosphates are among fire-proofing agents, but when ammonium is heated ammonia is evolved and phosphoric ated; this is a very strong acid and chars the l below its ignition temperature. A hot iron only slightly scorch an untreated fabric will ken the same fabric if it has been fireproofed.

, and perhaps most important of all, I believe nown fire-proofing process is fast to washing. plication the fire-proofing agent gradually ut, and the dangers attending the use of a ofed" material which after repeated washing its proof, are evident. The false sense of nay well make matters worse.

re some fire-retardants on the market; one of popular in America, is a mixture essentially of mmonium sulphamate and 15 parts ammonium e. But I believe that no known agent will on or winceyette fabric fire-proof after repeated and all adversely affect the desirable attributes ile material. Usually the textile manufacturer luctant to adopt a "functional finish" which iseful purpose; the almost universal application ase-resistant finish to spun rayon is an example Manufacturers and finishers have not adopted of finish for cotton and winceyette fabrics for reason that no satisfactory process is known.

is, however, another line along which the of providing children with flame-proof clothing attacked, and that is by the manufacture of rom fibres other than cotton or viscose rayon. acetate has for many years been used for d enormous quantities of cellulose-acetate rayon e. The raw material is cellulose, usually from nters or wood-pulp; but the substance has been d during manufacture. The acetylation is a mical combination, so there is no possibility acetyl content being reduced during washing leaning. The chance of a cellulose-acetate being considerably consumed by accidental with an electric fire is extremely small; fabrics om mixtures of wool and cellulose acetate e even less dangerous. Cellulose acetate is made rm of continuous-filament "artificial silk," and the form of cut staple—i.e., filaments cut into of one or two inches and then spun into a yarn same way as cotton. Garments made from -acetate rayon, or from mixtures of it with wool, e normal attributes of a good textile material, less inflammable than most. If such fabrics are into a hot fire, they will burn away: but if only locally the flame will sometimes extinguish It appears, in fact, that the use of cellulose- staple-fibre rayon, instead of cotton, would the danger of injury through clothes catching

possibilities present themselves, but are hardly for immediate adoption. Thus, many of the res, particularly those made from chlorinated ompounds, are fireproof. 'Pe Ce,' a heavily ted vinyl-chloride polymer, was used by the s for fire-resistant clothing for their flying el. 'Saran' and 'Velon,' which are essentially ylidene chloride, are fire-proof; but these fibres sture-resistant, they will not absorb perspiration, y cannot be ironed normally; they are usually red unsuitable for indoor wear, and particularly erwear; at present they are quite unsuitable for 's wear; and it is doubtful if they are obtainable, in the United Kingdom, in large quantities. In future it may well be that wool will be diluted (for cheapness) not with cotton but with regenerated protein fibres, which will be much less inflammable than cotton. Already 'Vicara' (made from maize protein) is obtainable in America, and 'Ardil' (made from ground-nuts) is being made on a pilot-plant scale in Scotland. But these are for the future—they offer no immediate solution to the problem of providing large quantities of non-inflammable material.

'Nylon,' as your contributors note, is useful; and, when large quantities become available in staple form at a low price, will undoubtedly be used for wool mixtures. For the present, the substitution of cellulose acetate for cotton and viscose rayon appears to offer a reduction of the fire risk.

Harrogate. R. W. MONCRIEFF.

NATIONAL COAL BOARD

SIR,—I read with interest the article on the Mines Medical Service in your Students' Number (Aug. 27).

The last paragraph, which purports to describe the responsibilities and achievements of the National Coal Board in the field of health, does less than justice to the considerable developments which the board has made since Jan. 1, 1947. As the article says, the board has a statutory duty "to secure the health" of the people it employs. To this end the Board decided, in 1947, to establish a medical service for the industry along the lines of the best practice in other industries. It was to provide pre-entry and other medical examinations first, and on occasion further treatment of accidents, the first treatment of illness arising at work, consultation in certain cases, advice on environmental conditions, supervision of hygiene and working conditions generally on the surface and underground, and so on.

The first seeds of a service had been sown by the Ministry of Fuel and Power in their medical treatment centre scheme, but when the National Coal Board took over the industry no medical treatment centres had yet been completed, and the industry employed only three full-time doctors, a number of part-time doctors, and 22 State-registered nurses. The National Coal Board by now employs 25 full-time medical officers, 66 State-registered nurses, and a considerable number of part-time doctors. Fifteen medical centres have been completed, and at fifty-one collieries existing buildings have been adapted to provide accommodation for this service. But for the request of the Prime Minister in June, 1949, when he set up the Dale Committee, that industries should withhold any major developments of their medical services, much greater developments would by now have taken place.

The scientific department of the National Coal Board is contributing to research on medical and other human problems in the industry. The rehabilitation centres and other health activities of the Miners' Welfare Commission are now coördinated with the National Coal Board.

Whilst acknowledging the very valuable work the Mines Medical Service of the Ministry of Fuel and Power has carried out in the past and continues to carry out, your article hardly makes clear the fundamental difference in responsibility between this service and that of the National Coal Board.

The Ministry of Fuel and Power medical officers are primarily concerned with the supervision of the industry with respect to the various statutory requirements on health and advising the Minister on various professional matters. The responsibility for executive action in securing the health of persons employed is that of the National Coal Board, and this responsibility the Board has fully accepted.

National Coal Board,
London, S.W.1.

ERNEST H. CAPEL
Chief Medical Officer.

STUDENT HOUSE-APPOINTMENTS

SIR,—In your issue of Aug. 27, a peripatetic correspondent bemoans the fact that medical students are sometimes allowed to deputise for qualified residents. As a student who has done such work during the summer vacation, may I suggest three excellent reasons for the continuance of this practice:

1. It adds a few more bricks to the edifice of experience. Your correspondent thinks that there is ample time, after qualifying, for perfecting the technique of giving a transfusion and performing a lumbar puncture. But surely a little more attention to practical work during student days with less anxiety over theory and the more rare diseases would make for greater competence.

2. Many students find it necessary to replenish their depleted coffers during the summer vacation. If they must work, it is surely best for them to work in their future profession.

3. For eight months of the year students grind away at theory, with very little practical work; and the [illegible] cquiring a little practical experience [illegible] energy.

True, our teachers aim at producing the best doctors. but "technical competence" is every bit as necessary as "basic understanding." In one we use our hands, in the other our heads; the master craftsman uses both.

MEDICAL STUDENT.

THE MEMBERSHIP

SIR,—I should like to express general agreement with the views given by Professor McMichael in your issue of Aug. 27.

I have for many years tried in the overseas Commonwealth to impress on universities and doctors the dictum that "higher qualifications" should be obtained—if at all—two or three years after initial graduation *in the same university,* and that expensive visits to Europe and America should be used for real postgraduate work with no examination in view.

In the overseas Commonwealth the standards of higher-diploma examinations in England are grossly exaggerated and the kudos accorded to the successful "Europe returned" candidate is wholly absurd.

So far as the M.R.C.P. London is concerned, the lowest age of entry was reduced from 25 to 23 years in recognition of the fact that young men capable of passing the examination were being kept back by the then existing regulations. When I appeared for the membership, a fellow-candidate, who had just reached his twenty-fifth birthday, had for some time been conducting a successful M.R.C.P. coach-class, and he passed along with some of his middle-aged pupils! The Royal College of Physicians has performed a real service in revealing the fact that the membership is not the recondite and mysterious qualification which many had supposed. The London College is to review its decisions in two years, and the regulations of the sister college in Edinburgh might be examined with advantage. Many of my former medical colleagues in India were M.R.C.P. Lond. and Ed. I think they derived more benefit from the Ed.!

Professor McMichael says with truth that study for examinations cramps and harasses excellent young men from the Dominions. Unfortunately some of them are only too willing to be so harassed.

Some years ago an appeal[1] which I made in India for the provision of higher degrees and diplomas in all Indian universities—"Indian degrees for Indian graduates"—met with enthusiastic and almost unanimous approval in both the medical and lay press—English and vernacular. The final paragraph was in close accord with Professor McMichael's thesis:

> "Let us get rid of the prevailing tendency to insist on overseas diplomas rather than on overseas experience, on contact with coaches instead of creators, and wi instead of inspiring leaders. Let those who sail do so in order to reap a rich harvest of the world of advanced knowledge rather than to scratch over which they have already ploughed."

I noted with pleasure in the *Times* of Aug. Nuffield Foundation travelling fellowships for A were "not available to persons who wish to the M.R.C.P. or F.R.C.S." I have hopes that one day impose a similar ban on her many travelling postgraduates.

PROS AND CONS

SIR,—In his comment on my article of Ex-Examiner (Sept. 3) confuses the act of with the pleasure derived from the amenities are so generously provided for the visiting e My delight in this hospitality, punctuated often with conviviality, is not less than your corr but this does not affect my appraisal of exam

It is not difficult to imagine more congenial stances than those offered by an examination for his "sense of isolation as a provincial teacher", least as much might be said of the "s experience." But perhaps Ex-Examiner prefers his pleasures sadly.

The University, Glasgow. STANLEY AL

MALLEOLAR FRACTURES

SIR,—I should be grateful if you would allow reply to some points raised in your annotation of

It is true that the os calcis and astragalus form a rigid lever until the limit of mobility subastragaloid joint has been reached; but ab I believe they do. As one pictures this occ becomes clear that the centre of rotation lies bel ankle-joint, and it is in this that my explanation mechanism differs from the conventional one.

The annotation says: "External rotation of is responsible for the commonest of the fractures." But is this so? I cannot say that experienced or observed this form of strain at quently, and cannot think of many occasions in life or in sport where one's foot undergoes this rotation. Here again, I believe, a theoretical m has been thought of first and the clinical facts ha fitted into the picture. This, incidentally, would my answer to Mr. Bonnin (Aug. 20). I cannot that it is right so persistently to ignore statements.

Rotherham Hospital. E. G. H

OVERDOSE OF AMPHETAMINE

SIR,—Dr. Worsley's note last week (p. 445) me to report an unusual experience with a pati took an overdose of this drug.

Six years ago a young man, aged 26, was found to right-sided pulmonary tuberculosis. He was trea artificial pneumothorax and has had periodic refill months ago the left lung was found to be affected. was admitted to a hospital where he was given a tw course of streptomycin injections. While in ho appeared depressed and was given amphetamine tab

On the morning after he arrived home he swallowed a hundred tablets of amphetamine, each contain of the drug, which he had brought home from the Several hours later his relatives found him perspiring His eyes were staring, and he was very restless, conf delirious but not unconscious. His private doctor wa and attempted stomach lavage, but not much suggesting the presence of dissolved amphetamine ta obtained. His clinical condition did not give rise t anxiety, so he was kept under observation at home. Ad to hospital became necessary later in the day, suddenly jumped out of a first-floor window and in spine; he did not lose consciousness.

---

PRICKLY HEAT

I was very interested in the article by Dr. d Dr. Mole in your issue of Aug. 13.

medical officer in Massawa during the late war, d that my wife and I and my batman, who did the daily salt tablets, were the only Europeans not suffer from prickly heat. I advised some of onal friends privately to stop taking the tablets, r skin cleared up quickly. I have never had more patients! **P. Robinson.**

WHY NOT GENERAL PRACTICE?

–I am sure that all thinking men and women gratulate you on the able leading article of ', which throws into bold relief the points I have in *State Medicine or What* and *Your Doctor of ure.*

so many years ago, at an annual meeting of men in London, I suggested that in the clinical g of students much more attention should be to the treatment of such subjects as bronchitis aged, infantile diarrhœa, and the infectious and that less heed should be paid to the rarer s often seen in the wards of a teaching hospital. reak with tradition was greeted with cries of wn." Times have changed.

the institution of the National Health Service as been a scramble for higher diplomas and st appointments. How much better it would be terms of service for general practice were made attractive with those for specialist appointments, the best brains might be attracted to that branch icine. After all, general practitioners are the shock of medicine, on whom depends the success of the . As the Spens report observed: "It would be ous to the profession and to the public if general e were recruited from the less able young s." And did not you yourself say[1]: "To be -class G.P. is harder than to be a competent ist."

ould like to readvance my argument, in *State ne or What*, that the usual road to specialist tments should be through general practice in the stance. Not only would the future specialist a practical knowledge of the difficulties of the ut the G.P. would also appreciate the trials of the ist; and thus a new and profitable harmony be created. All would subsequently follow their nd with the creation of chairs in general practice ay would be open for the most able, if they so desired, to become specialists in general practice without any financial loss compared with colleagues in other branches.

Worthing. **Harold Leeson.**

HYPERSENSITIVITY TO NORADRENALINE

Sir,—During a series of experiments on the effects of intravenous administration of mixtures of *l*-adrenaline and *l*-noradrenaline, one subject (R. F. W.) was found to be remarkably sensitive to *l*-noradrenaline but normally sensitive to *l*-adrenaline.

Infusion of 8 µg. of *l*-noradrenaline and 1 µg. of *l*-adrenaline per min. for $4^1/_2$ min. raised the blood-pressure from a resting value of 130/95 mm. Hg to a peak value of 230/150 mm. Hg, and slowed the pulse-rate from 74 to 54 per min. The subjective sensations were extremely violent pulsating occipital headache with some photophobia and stabbing retrosternal and pharyngeal pain, all of which were accentuated with each heart-beat. The infusion was stopped when the subject complained of the unbearable headache, but the hypertension declined slowly and sixteen hours later the diastolic pressure was still 110 mm. Hg (normally 90–95). As an intracranial hæmorrhage was feared, a clinical examination (R. S. A.) was made 50 minutes after the onset of symptoms. There was pallor, profuse sweating, and vomiting, but no clouding of consciousness or signs of meningeal irritation. There was no evidence of any lesion, and severe cerebral congestion was diagnosed. Eighteen hours later an electrocardiogram and electroencephalogram were both normal, and the subject was left with a slight occipital headache.

Equivalent amounts of noradrenaline administered to all our previous subjects (six subjects in 11 experiments) caused no subjective symptoms and the rise of systolic or diastolic pressure was less than 20 mm. Hg. Barcroft and Konzett[1] have also found that doses of *l*-noradrenaline of 10–20 µg. per min. caused negligible symptoms.

This preliminary communication is made to warn other workers using noradrenaline of the possibility of individual hypersensitivity to the drug.

"FOOLPROOF" BLOOD-TRANSFUSIONS

Sir,—I disagree with the statement made by Dr. Wiener in his letter of June 18 that "there is no longer any excuse for using the dangerous techniques necessary for transfusing unmodified blood."

During the past ten years I have given more than three thousand direct blood-transfusions, and I consider that there are occasions when not only is there a good excuse for giving unmodified blood but a direct transfusion is life-saving. I refer to cases in which there is recurrent hæmorrhage, and in particular to hæmatemesis[2] whether due to peptic ulcer or blood dyscrasia.

I first became interested in the transfusion of unmodified blood when a patient with hæmophilia continued to bleed despite repeated transfusion of fresh citrated blood, but stopped bleeding immediately when a direct blood-transfusion was given. Since then I have found on numerous occasions that as a hæmostatic unmodified blood is preferable to citrated blood, whether fresh or from the bank.

The main objection which Dr. Wiener raises to direct blood-transfusion is that there will be a dangerous rise in venous pressure. In cases of hæmorrhage I have never observed clinical evidence of an abnormal rise in venous pressure. In chronic anæmia there is such a possibility, but it occurs with both direct and indirect transfusion. In indirect transfusion the rise in venous pressure was found by Loutit, Mollison, and van der Walt [3] to be approximately proportional to the amount of fluid given, and they state that the rate of transfusion played a less important part although pressure rose more often at the faster rates.

---

[1] Leading article, *Lancet*, 1947, i, 25.

[1] Barcroft, H., Konzett, H. *Lancet*, 1949, i, 147.
[2] McLean, J. A. *R. Melb. Hosp. clin. Rep.* 1947, 18, 14.

On two occasions, when direct transfusion was given to patients suffering from chronic anæmia there has been increased venous pressure with symptoms of cardiac embarrassment; these symptoms were immediately relieved by venesection. The incidence of this complication in my series was less than 1%. In giving a direct transfusion, the operator is at hand if such symptoms should arise; and the condition is readily relieved by inserting a transfusion needle into a distended vein and withdrawing a few ounces of blood.

The technique of direct transfusion is difficult, but with practice in the use of a Julian Smith rotary pump and transfusion needles which are highly polished on the inner surface, the operation becomes simple, smooth, and effective.

With regard to the risk to donors, I have never seen or heard of a case in which there was transmission of infection. With the rotary-pump method infection would be due to negligence. On the other hand I have observed the accidental introduction of air into a donor's vein while blood for indirect transfusion has been collected into a bottle by gravity flow [4]—not into a vacuum flask, which Dr. Wiener mentions as an explanation for such a mishap.

Melbourne. John A. McLean.

EXPERIMENTS ON ANIMALS

Sir,—We are not out of sympathy with the views expressed by your correspondents of Aug. 6 or with your editorial comment in the same issue. We wish, however, to draw attention to a recent experiment on human beings.

In The Lancet of Jan. 22, there appeared a report under the title "Effects of Agenised Flour on Man." This described work designed to test what is a normal constituent of our diet in this country for toxic or other effects. The work involved the elimination of agenised flour from the diet of an experimental series of human subjects and their comparison with controls. To this there can be no objection. The investigators went further, however; for, finding that their control series were eating flour agenised at a level well below the maximum for commercial flour, they performed the additional experiment of *increasing* the dose of the potential poison until it reached this maximum.

Now the experimental subjects were boys aged 10–15 years from a residential school almost all of whose pupils came from homes that were social failures. They cannot therefore be regarded as being above "the age of consent" for the purposes of experimentation, nor is there any suggestion that their consent was asked or obtained. In our view the conduct of this experiment is, in consequence, open to grave objections, and the precedent it provides should be generally renounced.

The fact that the increased dosage was given at all shows that the investigators recognised that it might have some effect. What that effect might be can only be guessed from the original work on dogs and ferrets. In the light of what the authors call "the lack of knowledge of the reversibility of any changes which might occur" (in dogs) the second part of their experiment was in fact a risk to the health of helpless children. We fully realise that the maximum dosage given could be found in a commercial flour. The report makes it plain, however, that "Considerable difficulty was experienced in obtaining sufficient quantities of the flour agenised at 12 g. to the sack"; and it must be presumed that such high levels are very rare in normal diets.

May we hope that in future only volunteer be used in experiments designed to estimate the of treatments suspected of being dangerous to

Dunca

Bickley, Kent. D. R. N

*** This letter has been shown to the author paper referred to, who replies as follows:

"No exception can be taken to the ethical expressed by Dr. Leys and Mr. Newth. These fact scrupulously observed both in the original of the experiment and in subsequent mo Although this is not expressly stated in our American workers had shown before we change to the flour of higher agene content tha higher levels of agenisation are harmless to We ourselves had confirmed this in adult v —Ed. L.

POLIOMYELITIS AND TONSILLECTO

Sir,—The death of two brothers from polioen following tonsillectomy, to which you ref week, recalls an equally tragic case reported and Toomey.[1] Of a family of 6 children, 5 who went tonsillectomy on the same day all developed poliomyelitis; 3 of them died while the parents sixth child remained well. There was at the a low incidence of poliomyelitis in the district they lived.

There are, of course, other risks associated operation, and it would seem justifiable to ad apart from poliomyelitis or other epidemics, that of the same family should not undergo tonsillec other non-urgent operation at the same time.

Keith

London, W.10.

KEEPING BUSY

Sir,—There are two things wrong with the Act as it stands which any doctor can readily see for

1. Before July 5, no sickness benefit was paid injured. As soon as the case was settled in court common for the plaintiff to return to work. Now, benefit is not affected by damages recovered at co with the result that it will be virtually impossible to to work any man who is suffering from that common compensation neurosis. He will be paid for being n

2. Between the ages of 65 and 70 a man loses his full if he earns more than 20*s*. per week. It is a common see a man between those ages do no work, but at 70 he on a new lease of life and takes on jobs within his ca

What a tragedy in these days of insufficient lab waste the energy of these men who, but for social would keep themselves busy—aye and happier the pensioner keep his pension regardless of his and good luck to him.

C. H. F

Braintree, Essex.

*** Dr. Fagge raises two interesting points is some confusion, however, in the presentation first point. Presumably he is referring to injury under the National Insurance (Industrial In Act, and not to ordinary sickness benefit un National Insurance Act. In injury benefit, as in s benefit, the doctor through his certificate is of the arbiter as to incapacity. At the end of the benefit period—which in any case is limited to 26 w residual disablement, if any, is assessed by a board and a percentage award made in suitable In substantial injury cases the award takes the f a disablement pension. The latter is payable r of earnings and thus work is encouraged. The m common law claims, in occasional cases wher injured worker is alleging negligence on the part employer, is of course unconnected with the in scheme. Dr. Fagge's second point is discussed leading article on p. 469.—Ed. L.

Notes and News

FLIES

The average doctor knows very little about flies beyond the need to exterminate those which contaminate food; and then probably he does not know how they contaminate it, unless he has attended R.A.M.C. lectures. If he is middle-aged he has probably read his Shipley,[1] and if he has served in tropical or subtropical areas he is probably acquainted, through a War Office manual, with the vectors of such fly-borne diseases as malaria and phlebotomus fever. If he has a penchant for entomology as a hobby he has probably studied Imms[2] and may carry Sanders[3] in his pocket. But, if he has wanted to study flies in this country seriously, he has met with great difficulty in identifying them, because no key to all the known British diptera (of which there are more than 5000) has yet been published. This defect is now being remedied by the Royal Entomological Society of London, which is publishing ten volumes of *Handbooks for the Identification of British Insects*. The volumes are issued in separate parts at 7s. 6d. each, and vol. IX, part 1, an introduction and key to the families of diptera by H. Oldroyd, is one of those which can now be obtained from the rooms of the Society at 41, Queen's Gate, S.W.7.

University of Cambridge

On July 30 the following degrees were conferred:

M.D.—*A. P. Bentnall, Richard Fletcher, *Arthur Leese, J. M. Lipscomb, *A. P. Norman, *T. P. Pattinson, *J. R. Squire.

M.B., B.Chir.—*Joseph Armstrong, *G. K. Barker, *Arthur Bates, D. A. A. Beardsmore, *P. E. Bodkin, *E. C. A. Bott, *J. F. Boyle, Billie I. Brown, *David Bulmer, *Janet F. C. Callow, E. A. Cooper, Patricia B. Corston, *G. A. Court, *P. J. Crosland-Taylor, R. D. Eagland, *M. A. Epstein, R. W. Fairhead, *E. H. R. Ford, *Donald Gough, *G. A. Gresham, Brenda M. Grimmett, *E. C. B. Hall-Craggs, *R. N. T. Higgins, *B. J. Hockey, *L. B. Hunt, *D. S. Kerr, L. C. Hurst, I. P. James, E. W. P. Jones, M. J. Kehoe, *H. P. Lambert, *A. J. Lane, *D. G. A. Leggett, *D. W. L. * By proxy.

University of London

Dr. A. C. Cunliffe has been appointed to the readership in bacteriology at King's College Hospital medical school. Dr. J. L. Malcolm has been appointed to the readership in experimental physiology at St. Mary's Hospital medical school. Mr. Joseph Rotblat, who is a doctor of physics and a master of philosophy of the University of Warsaw, has been appointed to the chair of physics at St. Bartholomew's Hospital medical college.

University of Liverpool

If there are sufficient applications a part-time postgraduate course will be held during the coming session in the department of obstetrics and gynæcology and in the hospitals associated with the clinical school. Applications should be sent to the Dean of the Faculty of Medicine, The University, Liverpool, 3, by Sept. 10. For details see our issue of Sept. 3 (advt. p. 21); in some copies this course was inadvertently advertised under the University of London.

University of Glasgow

On July 19 the diploma in public health was awarded to the following:

Muriel S. Alexander, J. R. H. Berrie, G. S. Carrick, Flora C. Cowan, N. R. Cowan, Agnes C. Davidson, Katharin I. Kerr, Ruth A. Keymer, Duncan Livingstone, Margaret J. Macarthur, Duncan MacInnes, Ann K. MacLennan, James Maxton, Agnes W. O'Gorman, Martha G. Robson, Betsy D. Scott, Mendel Silver, J. M. Wallace, Elizabeth M. Whiteside, Jessie E. Wilson, T. S. Wilson.

Middlesex County Medical Society

The annual general meeting of this society will be held on Friday, Sept. 23, at 4 P.M., at the Edgware General Hospital, Edgware, Middlesex, when Dr. J. L. Hamilton-Paterson will speak on Focal Hypersensitivity as a Pathological Syndrome.

---

1. Shipley, A. E. The Minor Horrors of War. London, 1915. More Minor Horrors. London, 1916.
2. Imms, A. D. Insect Natural History. London, 1947.
3. Sanders, E. An Insect Book for the Pocket. London, 1946.

Edinburgh Post-Graduate Board for Medicine

On Tuesday, Sept. 13, at 4.30 P.M., in the anatomy theatre of the University of Edinburgh, Dr. D. P. Cuthbertson will speak on Metabolic Responses to Injury.

Abortion Law Reform Association

The annual general meeting of the association is to be held on Wednesday, Sept. 28, at 6 P.M. in the Conway Hall, Red Lion Square, London, W.C.1. At 7 P.M. Dr. Eustace Chesser will speak on Society and Abortion.

Remuneration of General Practitioners

A deputation from the General Medical Services Committee is to meet Ministry of Health officials on Sept. 23, to discuss the Ministry's report on the remuneration of general practitioners. The contents of the report have not yet been announced.

British Council for the Welfare of Spastics

Dr. Earl R. Carlson, medical director of the School of Corrective Motor Education, Long Island, New York, and Pompano Beach, Florida, will speak at 5 P.M. on Wednesday, Sept. 21, at 1, Wimpole Street, London, W.1. At the end of his address, the American film *A Day in the Life of a Cerebral Palsied Child* will be shown.

Medical Photography at Manchester

The exhibition of medical photography, organised by the medical group of the Royal Photographic Society of Great Britain (see *Lancet*, July 9, p. 65), is to be shown in the museum of Manchester Royal Infirmary (enter by the front lodge, Oxford Road) from Oct. 3 to 8. The exhibition will be open from 9 A.M. to 6 P.M. daily, and on Saturday until 1 P.M.

Institute of Psychiatry, London

On Wednesday, Sept. 14, at 5 P.M., Dr. Warren S. McCulloch, professor of psychiatry in the University of Illinois, Chicago, will speak on Neurological Organisation for Motion. On Thursday, Sept. 15, at 2.15 P.M., Dr. E. Gellhorn, professor of neurophysiology in the University of Minnesota, will speak on Emotion from the Physiological Viewpoint. Both lectures will be held at the Maudsley Hospital, Denmark Hill, S.E.5.

British Medical Association

The association will award the following prizes during 1950:

Sir Charles Hastings clinical prize (50 guineas) is offered for the best essay on observations and experiences collected by the candidate in general practice.

Nathaniel Bishop Harman prize for research in consulting practice (£100) is offered for the best essay submitted by a consultant member of the staff or senior hospital medical officer of a hospital in Great Britain or Northern Ireland who is not attached to a recognised medical school.

Further information may be had from the Secretary of the association, B.M.A. House, Tavistock Square, London, W.C.1.

CORRIGENDA: *Royal Naval Medical Service.*—The note on this Service in the Students' Guide (Aug. 27, p. 392) erroneously stated that "medical and dental candidates must have had at least six months' experience in a house-appointment." This condition applies only to medical candidates.

Register of Speech Therapists.—In our issue of Aug. 27 (p. 400) this register, of which the 1949 edition has now appeared, was inadvertently referred to as the Register of Special Therapists.

Staph. aureus in the Nares of Children.—In Dr. Cunliffe's paper of Sept. 3 (p. 412), table IV should read as follows:

Age of child (days)	Maternal nasal carriage				λ^2
	Positive		Negative		
	No. of children	% carrying *Staph. aureus*	No. of children	% carrying *Staph. aureus*	
0– ..	12	*25·0*	8	*Nil*	0·8119

Dr. B—*her* doctor. No, Dr. B has heard nothing.

Dr. B to the Registrar, Blank Hospital:

ar Sir,—My patient, Mrs. A, was discharged from your
ital three weeks ago. I should be very glad to have a
t of your findings. Yours &c.

Registrar, Blank Hospital, to Dr. B:

Dear Sir,—I enclose a copy of the summary of the case-notes of Mrs. A, as requested. Yours &c.:

"Mrs. A, aged 44. Admitted under Dr. X for investigation of atypical abdominal pain. No abnormal physical signs. Barium meal, cholecystogram, fractional test-meal within normal limits. Conclusion: No organic disease."

Dr. B conveys to Mrs. A the sense of this uninformative document by saying that nothing serious has been found, but the seeds of doubt have been sown and have begun to germinate.

Meanwhile Dr. Z, the house-physician, a careful and conscientious young man, is reviewing his cases and comes across the notes of Mrs. A; her problem unsolved, no conclusion recorded about her, no instructions about her treatment. To be on the safe side she had better be sent for to come to outpatients, just once, to make sure that nothing has been missed. Mrs. A and her pain return to the hospital and are ushered into Dr. Y's room. But Dr. Y has just got his Membership and passed on to higher things. There is a new doctor in his place. "Of course he does not know my case," thought Mrs. A, but was too polite to say so. The new doctor had to start again from the beginning because—the case-notes were lost . . . .

Do not smile at this sad history. In whole or in part it is enacted and re-enacted daily. Can anyone be blamed for such a dismal outcome? None is beyond criticism, yet none specially deserves it, because they are all worthy doctors.

It is a case of the failure of medical coördination. The doctors are individually beyond reproach; the facilities for meeting all the patient's needs are well conceived and well provided; the mechanism of investigation and diagnosis is smooth and rapid. Yet after ten days Mrs. A left hospital worse off than she was on admission.

THE INGREDIENTS

Let us consider individual responsibility in this miscarriage of medicine.

First Dr. B, the general practitioner. Doctors of the hospital world should be the last to cast a stone at the practitioner who shoulders so many burdens from which they themselves are exempt. If the callow houseman has sometimes been scathing over the telephone to an experienced practitioner, let it be a thorn in his conscience for ever. To Mrs. A's problem Dr. B applied the routine which pressure of time and experience had proved safe and economical. It might be objected that five minutes' conversation would have unearthed the phobia that was causing Mrs. A's pain to persist; perhaps it would. Yet, on average, Dr. B's routine is found to be safer—and certainly more economical in time—than exploratory talks with each patient.

The conduct of Dr. Y was beyond reproach. If he could not make a diagnosis on the evidence available in the outpatient department, his duty was to admit the patient to hospital for further investigation. This he did, with the magic formula, "we will see you through."

Dr. Z is an entirely admirable house-physician; but his very conscientiousness led him to sow another seed of doubt in the fertile mind of Mrs. A. He was thus an unwitting party to the miscarriage of medicine.

The stature of Dr. X places him beyond criticism. As a member of the senior staff, his medical commitments have steadily increased with the demands made on his time by advisory and consultative bodies. At his teaching hospital his function is to teach. He lectures and demonstrates to undergraduates; his postgraduate assistants he deliberately leaves to their own devices. They have the backing of his full confidence: it is his method and has stood the test of time. But by thus standing aside from intervention in the affairs of the patients nominally admitted under his care he may make a subtle contribution to the failure of medical coördination.

These are the characters in order of appearance. But surely somebody is missing from the list of dramatis personæ? Where is the first assistant? Why has he played no part in the affairs of Mrs. A? We have been deceived. The first assistant has seen Mrs. A, discussed her history with the house-physician, examined her on three separate occasions, scrutinised her X-ray films and summarised her case-notes—with perhaps rather a vague notion of whose notes he was summarising. Meanwhile he has been so busy teaching students, working in the outpatient department, supervising the follow-up clinic, and dictating letters to doctors that we have hardly noticed his existence.

THE RECIPE

This is a sorry hash to have made of such excellent ingredients. We need a good recipe for putting them to better use.

Coördination is the answer. But coördination is not a magic formula to be breathed over the successive stages of medical effort; it is a highly practical matter demanding the thought, work, and constant attention of all concerned. Let us consider the opportunities for coördination that offer themselves while the patient is in circuit from her doctor, through the hospital services, and back to her doctor again.

The Appointment.—Dr. B decides that Mrs. A must go to hospital for an opinion. He rings up for an appointment. A triangular relationship is thus established between doctor, patient, and hospital through the medium of its appointments-clerk. This official immediately becomes a person of consequence instead of a mere clerical automaton. Efficient appointments systems are becoming commoner, and the wheels turn more smoothly. It is desirable that patients should be seen within a week of their doctor's request—sooner if their condition warrants it. So long as practice falls short of this ideal, a system of priorities is needed, the smooth working of which hinges on good relationships between practitioners and hospitals; the appointments office is here the point of contact.

When Mrs. A keeps her appointment, the hospital should demonstrate that virtue with which it is too seldom associated—hospitality. This is now a fashionable topic, and we need only emphasise that a little hospitality at this point goes a long way to ensure a good relationship between patient and hospital and encourage coöperation rather than antagonism.

The Interview.—To Dr. Y, the clinical assistant, Dr. X, according to the teaching tradition of which he is a part, has delegated special powers, in the certainty that, having been through the hospital mill, he will not make many grave mistakes in handling his patients. He may yet commit two pardonable sins—over-caution and lack of frankness. Dr. Y cannot make a diagnosis; that very fact is his strongest weapon for persuading Mrs. A to come into hospital. Prestige is seldom lost by a confession of pardonable ignorance, and a frank statement of his position by Dr. Y will contribute generously to Mrs. A's smooth passage through her hospital admission. A letter to Mrs. A's doctor is the last, but not the least, important of Dr. Y's duties.

The Waiting-list.—This is a necessary evil. While it exists it is essential that it should be administered scrupulously and not haphazardly. For the waiting patient it means everything, and many good relations have been soured by clerical, even medical, indifference and maladministration. However the waiting-list is managed, its supervision must be a doctor's responsibility; the old days of control by ward sisters and lay clerks must, in fairness to those valuable people, never return. If admission is delayed, the patient should not be left high and dry in anxious speculation; a friendly phone call or a postcard will not strain the nation's finances. The difficulties of domestic rearrangement should always be remembered.

Admission.—The point of view of the patient to hospital has been vividly presented by a contributor to THE LANCET,[1] and we can add to that excellent description. But some relevant of the doctor-patient relationship in hospital are here in more detail. The patient is bewildered number of doctors who profess an interest in her each have their special functions, and there is no why the patient should not be admitted to the She will be more coöperative if she is kept inf the trend of events, of the reason for her adm the nature of the investigations or treatment planned; for her mind is uneasy in this strange ment, and she is deeply anxious about the outcome of her illness. Reassurance is th constant necessity. It is often years before the qualified doctor realises the value of reassurance even feels that it is an intellectually dishonest in the absence of a complete and negative inve but experience will teach him otherwise.

The patient will be particularly impressed by weekly round, with all its circumstance and retinue. Without any desire to teach "the chi job we venture to emphasise the immense pot for good or ill of this outstanding event. It is the students who hang on his words. Behind the "the chief" as teacher must find common gro "the chief" as medical director by combining lated laisser-faire with a shrewd instruction a patient's future. Thereafter his first assistant indeed be his *first* assistant, and not merely his by interpreting his wishes and making the con the patient's treatment and disposal his personal sibility. There is nobody else to do it. It is bey capacity of all but the most experienced hou and must therefore fall fairly and squarely on assistant's shoulders.

This continuity of approach and unanimity of should be fortified by ward conferences that contributions of ward sisters, almoners, and toward the object of building up a comprehensive of the patient in her environment. The more her discussed in common, the less divergence of op there be. Neither indecision nor lack of unanimity communicate themselves to the patient.

Discharge.—This is the crucial event for the yet it is seldom recognised as such. Instead, she given her ration book and a kindly *good-bye* and to drift out of hospital uninstructed and uninf A properly conducted discharge is potent for go should be formalised into a routine, almost a cer Each patient should be privately interviewed, no layman or a ward-sister, but by the first assistant, equivalent, who has had the supervision of the Only thus will continuity be maintained and the distilled from the hospital admission.

The farewell interview should be the occasion recapitulation of what has been achieved; the tion of results should be as full as possible and language adjusted to the patient's grasp. Inst about the future should be clear and decisive; if attendance is necessary, an appointment sho arranged; if not, this is the moment to break patient's dependence on hospital. There should be for questions and complaints, and all doubts sho removed from the patient's mind. The teaching ho where the patient's discharge is often haphazard unorganised, have much to learn from the more cratic rule of the medical superintendent, who formalise the occasion into a time for focusing events and tying up loose ends. There is an analog

the filing-cabinet or even the waste-paper basket.

THE "BIRD-OF-PASSAGE" SYNDROME

eresting syndrome may be recognised in out-
lepartments, especially those of postgraduate
hospitals. Many will find the details familiar
see in the unexceptionable Dr. Y an innocent
nt in another medical miscarriage.

r of Dr. B's patients keeps her appointment at
linic. "The chief," with a class of students on his
ances briefly at the doctors' letters of introduction
gns the less promising patients to his clinical assis-
r. Y does his conscientious best, fails to elucidate
toms, judges quite rightly that admission to hospital
ssary, and initiates certain investigations. While
in progress, Dr. Y is admitted M.R.C.P. and elevated
heres of activity. His successor, Dr. Q, is as puzzled
uivocal results of Dr. Y's investigations as by the
symptoms; some vague central-nervous signs and
certainty about the fundi suggest the wisdom of a
logical examination to solve the problem of headache
the sphygmomanometer and electrocardiogram have
ttle light. The patient's growing anxiety is quelled
e with phenobarbitone. By a happy intervention of
e—happy for the patient—Dr. Q is laid low with
on the occasion of her next visit, and the chief,
fed, intervenes, not a moment too soon, with a
mopping-up operation, and rescues the patient from the slippery slope that leads to the department of psychiatry.

Autocracy is the only direct remedy for this state of affairs, but an undesirable one. A threefold alternative is suggested; first, the birds-of-passage themselves should be encouraged to cultivate an awareness of the dangers inherent in their office which may lead in all innocence to such unhappy results; secondly, "continuity of doctor" should be recognised as an essential rule of outpatient organisation and striven after whenever possible; thirdly, the traffic of difficult cases between clinical assistants and their chief should be facilitated by personal contact and after-the-clinic conferences.

CONCLUSION

This is not an account of every possible cause of breakdown in medical organisation, nor are all possible remedies suggested; but the picture drawn, if a little exaggerated in parts, may stimulate others to contribute from their own experience.

It is submitted that the full value of applied medicine is being lost through a failure of coördination. Medical technique and organisation are constantly improving, but the cement required to bind them into an effective whole is often lacking. If medicine is not to fail in its application, there must be better coördination at all levels. This can be achieved within the existing framework because it calls only for a change of attitude and a new awareness on the part of all the doctors concerned.

The "registrar class" will be aware that the lot must fall on them. Within the teaching-hospital framework, at any rate, this is the only possible solution. They are already a hard-worked, if not overworked, class, and there may be no room in their time-tables for the business of coördination as described above. In that case rearrangement of their duties and even an increase in their numbers may need to be considered. But they will do the job.

Who will take the lead in initiating this change of outlook and of practice? We look to our seniors to provide the directives and the inspiration. There must be such a change if we are to fulfil our pledge and "see the patient through."

I am indebted to Dr. Alastair Hunter for many stimulating thoughts on these topics and for the original sketch and title of the "bird-of-passage" syndrome.

TENSILE STRENGTH OF SUTURES

I. THE B.P.C. METHOD OF TEST

D. M. DOUGLAS
M.B.E., Ch.M. St. And., F.R.C.S.
LECTURER IN EXPERIMENTAL SURGERY IN THE UNIVERSITY OF EDINBURGH

THIS paper presents observations on the standard method of testing the tensile strength of sutures as laid down in the *British Pharmaceutical Codex* (1946). It proposes a modification which would help the surgeon to choose a suture with an effective tensile strength comparable to that of the tissue in which it is to be inserted.

B.P.C. METHOD

The Tensiometer

The *B.P.C.* specification for the tensiometer is as follows:

> "The machine for determining the tensile strength shall be of the dead-weight type having a constant rate of traverse of the movable jaw of 12 inches per minute and of a capacity such that, when the specimen breaks, the angle which the pendulum arm makes with a vertical line is between 9° and 45°. The clamps shall be of such design that not more than 25% of the specimens in any lot tested break at a point within 0·5 inch of either of the clamps." (*B.P.C.* Suppl. vi, 1944.)

Methods of Testing

Two methods of testing the suture on the tensiometer are used—the "straight pull" method and the "knot" method.

(1) In the "straight pull" method each end of a single strand of the suture is placed in the clamps, and the ends are gradually distracted until the suture breaks. The strain in pounds at the time of fracture is read off a calibrated scale.

(2) In the "knot" method a surgeons' knot—i.e., a square knot with a double turn on the first throw—is tied in the middle of a strand of the suture, the ends of the suture are clamped, and the test proceeds as before.

The value for the straight-pull strength is always *greater than that for the knot strength, in the rough* proportion of 100 : 70, because some of the fibres of the suture fracture at the acute kinks of the knot.

COMMENTS ON *B.P.C.* METHOD

A brief consideration of the two standard methods of suture used in *surgery—interrupted and continuous*—shows that in tissues a suture is never called on to bear the type of strain to which it is submitted in the *B.P.C.* test.

Interrupted Suture.—An interrupted suture is a loop of suture material completed with a knot, and in a wound the fracturing strain operates from within the loop. It is likely on theoretical grounds that the force required to break the loop will be considerably greater than that required to break either the single strand or the knotted strand. In fact, if the frictional resistance is zero, the strength of an interrupted suture should be equal to the sum of the strengths of a single strand and a single knotted strand.

Continuous Suture.—A continuous suture is a single strand of suture material anchored at each end of the wound with a knot. Except in contractile viscera the length of wounds varies but little, and it is clear that the chief stress on the suture is not in the longitudinal axis of the suture as it is in the tensiometer. In the standard abdominal incision the chief strain will doubtless be at an oblique angle to the suture. But the analysis of the site of greatest strain in a continuous suture and of the

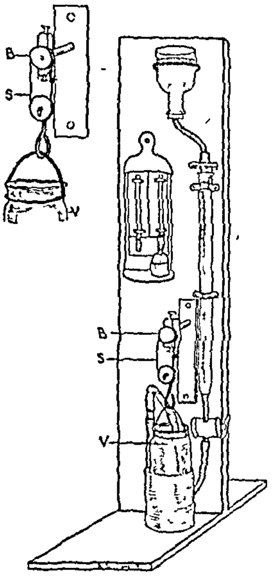

Fig. 1—Tensiometer described in text for testing tensile strength of sutures: B, fixed beam; S, suture; V, vessel. Strain is gradually placed on suture by increase of weight of mercury in vessel, which is filled by gravitation at relatively constant speed from burette. Method of applying suture is illustrated in small figure.

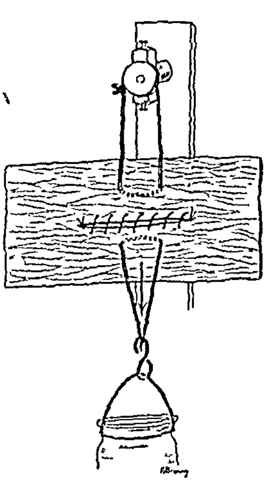

Fig. 2—Method of testing tensile strength of continuous suture. Greatest strain is applied at centre of incision, thus imitating greatest strain in operation wound.

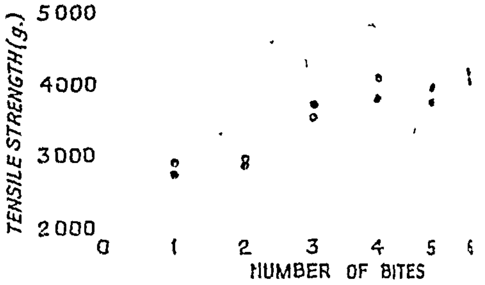

Fig. 3—Increase of effective tensile strength of continuo relation to increasing number of bites.

quantity of the strain is exceedingly complex to take into account such factors as friction, wound length, and the number of bites.

NEW METHOD OF TESTING

In the Wilkie Surgical Research Laboratory *tested the tensile strength of sutures* with an which consists essentially of a fixed beam, B

TABLE I—MEAN TENSILE STRENGTHS OF SUTURES BY *B.P.C.* METHOD OF "STRAIGHT PULL" AND STRAND" AND AS INTERRUPTED SUTURES

Suture material	Diameter (mm.)	Mean tensile strength in		
		B.P.C. method		Interrupted suture
		Straight pull	Knotted strand	
Silk	0·22	947	650	1402
Cotton	0·21	1187	826	2132
Linen	0·21	1892	1010	2562
Nylon	0·19	882	620	1332
Stainless steel ..	0·16	1452	1180	2571
Tantalum ..	0·08	376	300	630
Silver	0·15	997	600	1492

vessel, V, of known weight into which mercury run from a calibrated burette (fig. 1). The be tested was fixed to B and V, and, as the me into V, a strain was gradually placed on the which increased in proportion to the volume of in V. When the suture snapped, the stopcock burette was closed and the reading *taken.* The strength of the suture in grammes was taken to

T.S. = Vol. of mercury in ml. × 13·5 + wt. of V in g

When a continuous suture was to be tested inserted into a piece of leather in which an inci previously been made. The edges of the inc distracted by fixing two stout loops of heavy equidistant points of 1 cm. from the centre of the in distraction was then applied as before (fig. 2).

RESULTS

The mean tensile strength of a single unknotted of fine silk (calibre 0·17–0·2 mm.) was 947 g. Wh same suture was tested with a surgeons' knot tied middle, the mean tensile strength was 650 g of the former value). The mean value for an inte suture of the same material was 1402 g., or sligh than the sum of the first two values. Similar res noted for sutures of cotton, linen, 'Nylon,' stainles tantalum, and silver (table I).

When a *specimen of fine silk* was tested as a con suture, remarkable results were found (table II mean tensile *strength of the suture,* when seve of tissue were taken, was 4735·6 g., or about ten the "knot" strength of 488 g. When only two were taken, the mean tensile strength was still or six times the "knot" strength (fig. 3).

DISCUSSION

ults indicate that the tensile-strength values
y the *B.P.C.* may mislead the surgeon in the
suitable sutures. There is little doubt that
ign material left in a wound, the more readily
will the wound heal. It is therefore desirable
finest sutures which have the tensile strength
o hold the tissues. In the case of unabsorb-
s it would be reasonable to use material of
same tensile strength as that of the tissue

TENSILE STRENGTH OF SUTURES

II. LOSS WHEN IMPLANTED IN LIVING TISSUE

D. M. DOUGLAS
M.B.E., Ch.M. St. And., F.R.C.S.

THE use of unabsorbable suture material for the repair of large, direct, or recurrent herniæ has become increasingly popular (Maingot 1941, Edwards 1943, Douglas 1948, Moloney et al. 1948, Abel and Hunt 1948). It is obviously a matter of some importance to determine whether these sutures contribute permanent strength to a repair, and the present study was undertaken to investigate this point in the case of silk, linen, cotton, 'Nylon,' silver, tantalum, and stainless steel.

METHODS

Specimens of the sutures to be studied were tested in the dry state for tensile strength with the apparatus already described (Douglas 1949). The suture was in the form of a loop, completed by a surgical knot with the ends left long. During the test the suture broke almost invariably at or immediately adjacent to the knot. Lengths of the sutures were next implanted subcutaneously in the abdominal wall of rabbits, and the animals were killed with chloroform at monthly intervals. The sutures were carefully removed from the dead animals, dried, and tested for tensile strength as before.

There are two obvious sources of error in this method:

Variations in Tensile Strength.—Suture material varies considerably in tensile strength from strand to strand and even at different parts of the same strand (table I). This is particularly the case in the organic suture materials, the specimens of linen showing variations of 1104 g. from strongest to weakest. The metallic sutures are more uniform. To rule out errors from this source it is clearly necessary to submit a series of sutures to test and to have a large number of controls.

Water Content.—Organic suture materials lose tensile strength when moist, and it is therefore necessary to dry the sutures carefully after removal from the animals. This was done by placing the sutures in envelopes and keeping them at a temperature of 95°F for twenty-four hours. Note was made of the wet-bulb and dry-bulb reading at the time of the test, but readings were all within the *B.P.C.* range. It was impossible to be sure that the water content of the sutures after drying was the same as that before implantation, but, so far as possible, errors from this source were eliminated.

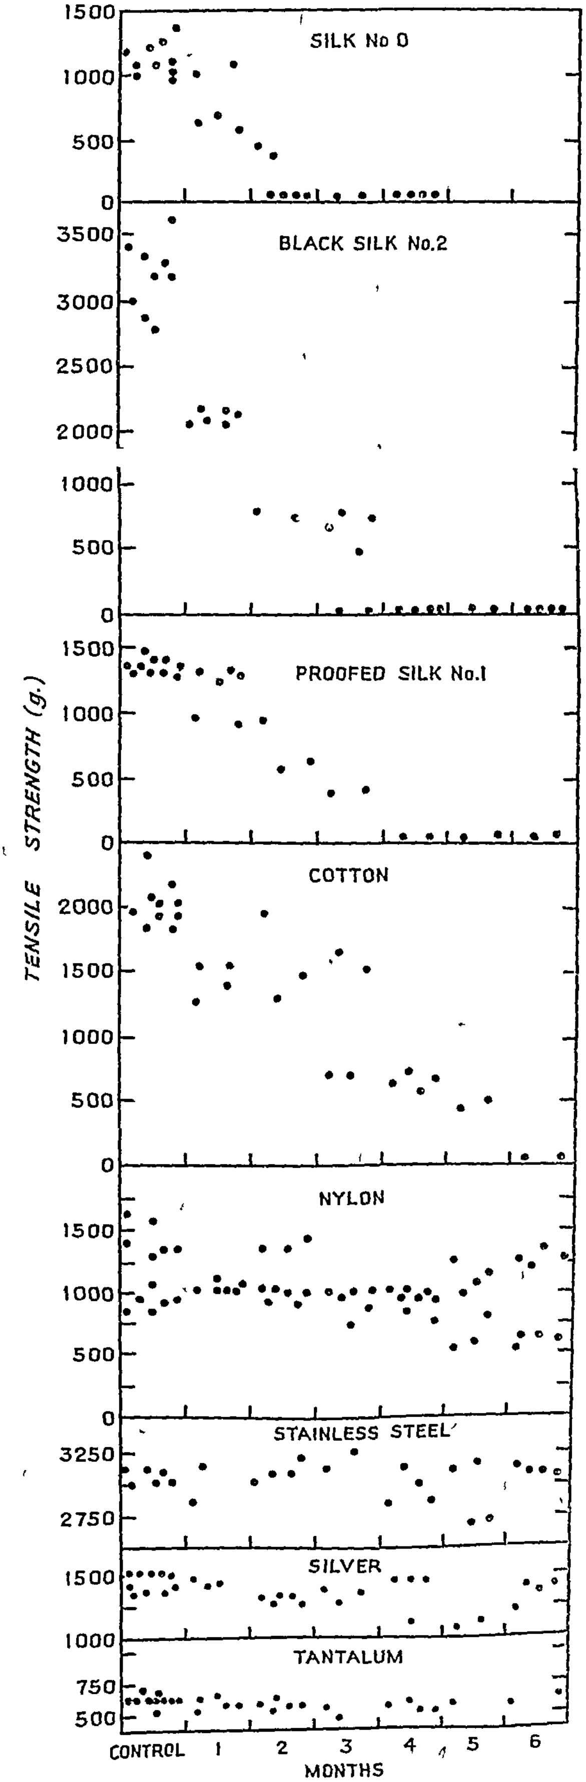
ORGANIC SUTURES

The results after implantation in living tissue are given in table II and the accompanying figure.

Silk.—Three types of silk sutures were tested: a no. 0 and a no. 2 unproofed silk and a no. 1 proofed silk suture. Both specimens of unproofed silk lost tensile strength rapidly in tissues and by the end of the second month retained only 13–20% of the original strength. By the end of the fourth month both specimens were so weak that they broke into small fragments when they were removed. The proofed silk retained its tensile strength slightly longer than the unproofed specimens. At the end of the fourth month it still retained about 30% of its original strength. However, each specimen which had been in tissue for over four months broke into fragments when removed.

Cotton.—Two specimens of cotton sutures were tested labelled "cotton no. 36" and "cotton no. 40." Little difference either in tensile strength or in calibre was found between the two, though they were supplied as different suture materials. Both lost tensile strength rapidly and at about the same rate as silk. By the end of the sixth month neither specimen retained enough tensile strength to be of value in a repair.

Linen.—The specimen of linen tested was labelled "linen 90" and had a calibre of about 0·21 mm. It had a tensile strength somewhat greater than that of silk and cotton of comparable size. Though it had lost tensile strength rapidly, at the end of six months it still retained about 30% of its original strength. At the end



Effect of implantation in living tissue on tensile strength of sutures. Each point indicates one test.

of the eighth month, however, its tensile fallen to 420 g. (15% of the control value)

SYNTHETIC AND METALLIC SUTURES

Nylon.—The nylon sutures tested sho variation in tensile strength. Control rea specimen labelled " Nylon no. 1 " varied fr 1612 g., and those in " Nylon no. 2 " varied to 1082 g. With this great overlap there was in regarding them as different sutures, and are presented together. Up to the end of t month no loss of tensile strength was dete the fifth month four of the specimens sho below the control range, and at the end of month four of the specimens showed a clear fal strength, while four were unaffected. The v noted in this group are no doubt due to original in tensile strength, but it is clear that the nylon is much less affected by tissues than is the of the organic sutures. At the end of the the mean tensile strength was 84% of the co

Stainless Steel, Tantalum, and Silver.—The sutures may be considered together. They all more uniform tensile strength than did the o materials, stainless steel and tantalum being constant in this regard (table I). Tensile s not appreciably affected in these suture six months' implantation in tissue. The m strength of stainless steel in the control s 2572 g., and the same value after six months was 2601 g. The values for tantalum were 628 g

DISCUSSION

Two aspects of this study merit some disc unsatisfactory state of numbering of sutures remarkable fact that a fairly heavy silk suture rapidly weakened in tissue until at the end of fo it has lost all its tensile strength.

Numbering of Sutures

The practice of labelling sutures with num doubt to give the surgeon some guide to the If this is so, manufacturers could not easily have a more confusing situation than exists at pr example, no. 1 nylon, silk, and catgut have diameters of 7, 9, and 23 thousandths of (0·18 mm., 0·2 mm., and 0·58 mm.). In th metallic sutures the position is even more since these are supplied according to the stan gauge, in which a diameter of 0 009 inch ((corresponds to a S.W.G. value of 34.

The most reasonable way of numbering sutu be to quote the diameter in thousandths of an i a suture of a calibre of 7 thousandths of an i have the number 7, whatever its compositi corresponds in size to catgut no. 5/0. A su calibre of 20 thousandths of an inch—e.g., ca —would have a number 20. Since it is only ve tionally that sutures of less than 3 thousand inch or greater than 30 thousandths of an required in surgery, the whole range of surgic whatever their composition, could be covere numbers 1, 5, 10, 15, 20, 25, and 30. The surg then know that any suture ordered as no. 15, wo diameter of as near 15 thousandths of an inch as manufacturing skill could achieve. The *B.P* a range of 3–4 thousandths of an inch in eac

This, then, would be a rational method; manufacturers and surgeons are on the whole tive in outlook, a compromise might be more a If all suture material were labelled accordi *B.P.C.* specifications for catgut, a more position would result. Silk no. 1 would then b 4/0, nylon no. 1 5/0, linen no. 90 4/0, and bewildering situation would be converted into though illogical, would be relatively simple to u

ile Strength in Silk Sutures

ıgs in the case of the organic sutures were since it is generally believed that a darn of the repair of hernia forms a permanently ework for a repair by fibrous tissue. The ate that, even in the case of a moderately reliance cannot be placed on its power to train after two months; linen and cotton any, better in this regard. The loss of tensile no doubt the result of a combination of cir-; the moist environment and the action of nts and histiocytes may be cited as some rs probably involved. But, whatever the ffect is clear: of the organic sutures tested ontribute permanent strength to a hernial

llic sutures, on the other hand, were as removed at the end of six months as when nserted. There is good evidence, therefore, materials can offer a strong and long-lasting for the growth of fibrous tissue in a hernial ided that they do not undergo fracture from ning.

ion of nylon is almost as good as that of the tures, though the great variations in tensile ake it a somewhat unpredictable material to Not being subject to work-hardening, it has vantages over metallic sutures for hernial uch mobile parts of the trunk as the epigas- m having a fine nylon mesh prepared which erior to tantalum mesh in the repair of these erniæ.

SUMMARY

of unabsorbable sutures commonly used in of hernia were implanted in the abdominal nals. At monthly intervals they were removed for tensile strength.

nic suture materials—silk, cotton, and linen— strength rapidly after the second month, and by the sixth month were either disintegrated or so weak as to have little power of reinforcing a defect.

In contrast, the synthetic material nylon and the metallic sutures—stainless steel, tantalum, and silver—lost little tensile strength, and at the end of six months were on the whole as strong as when inserted.

This evidence is taken to indicate that the organic suture materials cannot contribute strength to a hernial repair for longer than a few months, whereas sutures of nylon, silver, tantalum, and stainless steel may form a strong and long-lasting scaffold upon which the essential repair of fibrous tissue may develop.

INCIDENCE OF
PENICILLIN-RESISTANT AND STREPTOMYCIN-RESISTANT STAPHYLOCOCCI IN A HOSPITAL

PHYLLIS M. ROUNTREE
M.Sc. Melb., Dip. Bact.

EDGAR F. THOMSON
M.B. N.Z., F.R.A.C.P.

From the Fairfax Institute of Pathology, Royal Prince Alfred Hospital, Sydney, Australia

Barber (1947a and b), in studies on the occurrence of penicillin-resistant coagulase-positive staphylococci in patients in a London hospital, showed that the incidence of resistant strains rose from 14 to 38% in a year. Subsequently (Barber and Rozwadowska-Dowzenko 1948) the incidence rose to 59 in 100 cases. In the latter series there was evidence that a proportion of the resistant strains had come from patients infected in hospital. Streptomycin sensitivity tests were carried out on the last series of 100 strains, and 1 strain showed a resistance greater than that of the control Oxford strain.

It is well established that as many as 60% of normal people may be nasal carriers of coagulase-positive staphylococci, but less is known about the incidence of penicillin-resistant strains among such carriers. Voureka and Hughes (1949) examined 315 strains of staphylococci obtained from the noses of outpatients attending an asthma clinic and found 24 (7·6%) which were resistant to 1 unit of penicillin per ml. Of these strains 14 were coagulase-positive; 11 strains produced penicillinase; 13 did not, but it is not stated whether these were coagulase-positive or coagulase-negative strains. Martin and Whitehead (1949), who examined 50 medical students and laboratory workers, found a carrier-rate

Dr. Robert [illegible] Library

of 62% for coagulase-positive staphylococci; 6 (12%) of this group were carrying penicillin-resistant strains.

Observations made in the routine bacteriology laboratory of this hospital during the first nine months of 1948 suggested that many strains of *Staph. pyogenes* * isolated from various clinical conditions were penicillin-resistant. It was therefore decided to examine for penicillin sensitivity and phage type all strains of *Staph. pyogenes* isolated. As streptomycin was then just becoming readily obtainable for treatment, it was decided to test the strains for sensitivity to this antibiotic to obtain basic data for future comparisons.

The findings from October, 1948, to March 31, 1949, are here reported, together with observations on the nasal carrier-rate of *Staph. pyogenes* in the hospital staff and in an unselected group of the general population.

METHODS

Nasal swabs were taken with swabs moistened with a little nutrient broth. All material was inoculated directly on to blood-agar plates. Except where there were obvious differences in colony morphology or in hæmolytic activity, single colonies only were picked from each plate for coagulase tests, sensitivity tests, and phage typing. Coagulase activity was determined by the slide method of Cadness-Graves et al. (1943) or by the tube method. Phage typing was done by the method of Wilson and Atkinson (1945), except that the phage types are now designated by the phages to which they are susceptible. Sensitivity tests to the antibiotics were made by the streak method on blood-agar plates in the centre of which had been placed sterile discs of filter-paper to which were added 20 units of penicillin or 2 mg. of streptomycin. Control cultures of sensitive strains Oxford H or 313 were included on every plate. In the case of penicillin the strains were recorded as resistant if growth took place to the edge of the paper disc or to within 1 mm. of it. Some strains were encountered which were more resistant to streptomycin than was the control culture, but in no case did such strains grow up to the edge of the disc. Additional penicillin-sensitivity tests were made by the tube method with selected strains, large inocula of 0·1 ml. of a 1 in 100 dilution of a 24-hour broth culture being used.

RESISTANCE TO PENICILLIN AND STREPTOMYCIN OF STRAINS ISOLATED FROM PATIENTS

We examined 228 strains of *Staph. pyogenes* isolated from 196 patients. The resistance of these strains to the two antibiotics, the number of patients from whom they were obtained, and the number of phage types to which they could be assigned were as follows:

Antibiotic resistance	*No. of patients*	*No. of strains and % of total*	*No. of phage types*
Penicillin-sensitive ..	104 ..	107 (*47%*) ..	38
Penicillin-resistant ..	92 ..	121 (*53%*) ..	21
Streptomycin-sensitive ..	189 ..	216 (*95%*) ..	46
Streptomycin-resistant ..	7 ..	12 (*5%*) ..	6

Penicillin.—From 104 patients 107 penicillin-sensitive strains were isolated, and from 92 patients 121 penicillin-resistant strains were obtained. Thus 47% of strains were penicillin-sensitive and 53% penicillin-resistant. It will be noted that the ratio patients/strains was larger in the penicillin-sensitive than in the resistant group. This was because some of the resistant strains were obtained from surgical patients who had been long in hospital and had been swabbed more often. If the incidence of penicillin-resistant strains is calculated on the basis of patients rather than of strains, the figures are 47% of patients infected with penicillin-resistant strains and 53% infected with penicillin-sensitive strains.

Streptomycin.—Only 12 strains of streptomycin-resistant *Staph. pyogenes* were found in 228 cultures. These strains came from 7 patients. In 6 the mycin-resistant strain, which was of the same type as the original streptomycin-sensitive appeared after streptomycin therapy. The 7th had a cross-infection and had received no s

PHAGE TYPES OF STRAINS ISOLATED FROM P

Early in the investigation it was found that a able number of the penicillin-resistant strains react with any of the phages of Wilson and (1945) series. However, a phage was ob adaptation of phage 31 which proved of great identifying these strains. It is a citrate-sensi belonging to serological group B (Rountree lyses strains which are sensitive to phage 7 large number of strains which are insensitive to This phage is provisionally called 31b, and by it are called type 31b.

The number of phage types differentiated 107 penicillin-sensitive strains was 38, with no type predominating; 30 strains (28%) were not with the available phages. The phage types 121 penicillin-resistant strains were as follows.

Phage type			*No. of strains and % of total*
31lb. ..	..	..	50 (*41%*)
7/42b/47c	..	..	22 (*18%*)

7/47 ..	..	..	6 (*5%*)
15 other types	..	..	19 (*16%*)
Non-typable	..	..	11 (*9%*)
Total	..	..	121

11 strains (9%) were not typable with the phages. 75% of the resistant strains were a for by 5 phage types. The balance of 19 strains to 15 types. Type 31b was the predominant being isolated on 50 occasions from 38 patient 7/42b/47c came next in frequency, 22 culture obtained from 11 patients.

PENICILLIN-RESISTANCE IN RELATION TO PE THERAPY AND ORIGIN OF INFECTION

The case-records of the patients from whom resistant strains were recovered have been for information on the nature of the stap infection, its probable origin, and the relati penicillin therapy. In one case, that of an ou no history was available. 91 cases have theref classified in the following way.

If the resistant strains were isolated from p material obtained at the first examination of the after admission to hospital and before instit penicillin therapy, the infection was consi primary. Cases were regarded as having be infected in hospital when the resistant organis obtained from such situations as surgical sinuses, burns, or urine, which had previously s signs of infection, or had been infected with organisms or with a different phage type of lococcus. In 16 cases the data available were in to allow with certainty an assessment of the of the infection, and these are classified as of u origin. In 4 cases there was evidence of conve the strains to penicillin-resistance during therapy were 5 cases in which the strains were isolated routine examination of nose or throat swabs symptomless carriers. The case-records are as follows:

Origin of infection		*No. of cases*		*Penicillin ther isolation of re*
Primary	..	12	.. ..	0
Hospital cross-infection	..	54	.. ..	39
Conversion during treatment	..	4	.. ..	3

Uncertain	..	16	.. ..	12
Total ..	..	91		54

---

* In using the name *Staph. pyogenes* we follow Cowan and Shaw (1949) in meaning coagulase-positive staphylococci which may or may not produce pigmen

n was considered to be primary in the following

Type of infection	*No. of cases*
Otitis	3
Carbuncle	1
Abscess	2
Cystitis	1
Paronychia	1
Infection of hands	2
Infection of carcinoma of skin	2
Total	12

of these infections developed in nurses there 8 cases in this series of 196 in which infection cillin-resistant strains took place with certainty ie hospital.

4 cases probably cross-infected in hospital the greater part of the material. Of the 39 who had received penicillin before isolation of ant strains, 30 had infected surgical wounds, as the 15 who had not been treated with penicillin. 0 surgical patients who had received penicillin ant organisms were isolated at the first swabbing, done when wounds showed signs of breakdown harge of pus, or because of delayed healing. nsidered that such cases were infected with a lready penicillin-resistant at the time of its to the wound, and that the resistance had not d as the result of penicillin therapy of the concerned.

ncidence of phage types in the 54 cases of cross- was as follows:

Phage types	*No. of cases*
6/42b/47c	1
7/42b/47c	6
31/42d	1
31a/31b	1
31b	31
42b/42e	1
42b/47c	4
42d	1
42e	1
47	2
47/47a	1
Non-typable	4
Total	54

be observed that 31 (57%) of the strains belonged 31b. Some of these type 31b strains were tested cillin resistance by the tube method. All produced nase and grew in concentrations of 200–500 units cillin per ml. It is therefore obvious that even oses of penicillin will not control infection with rticular strain. There can be no doubt that these in-resistant strains are fully pathogenic. In one oss-infection of a mastoidectomy wound with a lb strain was followed by a cerebral abscess with sult.

cases of uncertain ætiology included 5 patients nfection of the lungs, who had received penicillin isolation of the resistant strains. Of the 4 patients d received no penicillin, 3 may have been infected pital; they had pyoderma, conjunctivitis, and opneumonia, all infected with the type 31b strain.

CARRIER-RATE IN HOSPITAL STAFF AND GENERAL POPULATION

ing established that a large proportion of penicillin- nt strains were being isolated from patients cross- d in hospital, and that two phage types (31b /42b/47c) were the predominant organisms in these ions, we investigated the nasal carrier-rates of strains in the hospital staff.

February a survey was made of the nurses and rs. 200 nasal swabs were taken, 187 from nurses 3 from resident doctors. These people were distri- throughout the hospital, 17 wards being sampled. complete nursing staff of the operating-theatres wabbed, but in other wards only a sample of the was swabbed.

The results of this survey showed that a control group of the general population should also be examined. It was thought desirable to obtain a randomised sample rather than a homogeneous group of preclinical year medical students or of hospital outpatients. Through the courtesy and cooperation of the director of the Red Cross Blood-Transfusion Service we were allowed access to an ideal control group in the blood donors. These people do not visit the hospital to give their blood and are drawn from all classes of the community and from many parts of the city. From these blood donors 200 nasal swabs were therefore taken.

The results were as follows:

	Numbers swabbed	*Carriers of Staph. pyogenes*	*Carriers of penicillin-resistant strains*
Hospital staff	200	105 (*53%*)	64 (*32%*)
Blood donors	200	90 (*45%*)	8 (*4%*)

Among the hospital staff 105 people yielded *Staph. pyogenes*, a carrier-rate of 53%. The carrier-rate of the blood donors was 45%. There is no significant difference in these rates. When, however, the figures for penicillin-resistant strains are examined, a striking difference is observed. In the hospital staff 64 of the 200 showed penicillin-resistant strains, a carrier-rate of 32%, compared with 8 among the 200 blood donors, a rate of 4%. This difference is highly significant. ($\chi^2 = 53{\cdot}12$: $P < 0{\cdot}001$).

If the nasal carrier-rate of the hospital staff is converted to a percentage of the 105 carriers of staphylococci, 61% of carriers had penicillin-resistant staphylococci in their noses.

The phage typing of these nasal strains also yielded results of considerable interest. The penicillin-sensitive strains belonged to many phage types, with a large percentage (31%) of non-typable strains. Many of these non-typable strains, though coagulase-positive, were poor pigment producers. The distribution of phage types among the penicillin-resistant strains was as follows:

Phage type	*No. of strains*	
	Hospital staff	*Blood donors*
7/42b/47c	8	0
29	0	1
31b	42	1
42b/42c	1	0
42b/47	1	1
42b/47/52	1	0
42b/47c	7	1
47	0	4
Non-typable	4	0
Total of strains	64	8
Total of types	6	5

Here again, as with the strains from patients, there is a predominance of two types among the hospital staff. Type 31b was isolated from 42 nurses (65%), and type 7/42b/47c from 8 (12%). There were 7 carriers of type 42b/47c, which had also been found in 4 of the 47 cross-infected patients. The number of penicillin-resistant strains from the donors is too small to yield much information on phage-type incidence; however, only 1 out of 8 strains belonged to type 31b.

When the distribution of the nasal carriers in the hospital staff was arranged according to wards, it was found that the carriers of penicillin-resistant strains were scattered over the whole hospital, including the operating-theatres. There were carriers of type 31b in all but three wards. Since only a proportion of the staff was swabbed, there were probably carriers of this type in every ward.

None of the 195 strains of *Staph. pyogenes* isolated was more resistant to streptomycin than the Oxford strain of staphylococcus. No nasal carrier of β-hæmolytic streptococci was found in the 400 people swabbed.

DISCUSSION

Examination by the phage-typing method of penicillin-resistant strains of *Staph. pyogenes* isolated from infections of patients in a general hospital and from nasal carriers in the nursing staff of the hospital and in a sample of the general population has yielded results which throw some further light on the ecology of these organisms.

In 196 patients only 12 cases were found in which the clinical condition could be certainly ascribed to a primary infection with penicillin-resistant staphylococci and in which the patient had received no previous penicillin therapy. Since 4 of these infections occurred in members of the hospital staff, there were only 8 cases in which infection occurred outside the hospital community. This incidence of infection with penicillin-resistant strains accords well with the nasal carrier-rate of 4% found in the blood donors examined.

In the present series there were cases in which penicillin sensitivity was converted or may have been converted to resistance as a result of penicillin therapy. However, most of the patients yielding penicillin-resistant strains acquired these strains by cross-infection while in hospital. There were 44 cases of infection of clean surgical wounds with penicillin-resistant staphylococci, compared with 12 cases of wound infection with penicillin-sensitive strains.

The very close agreement between the distribution of phage types among the penicillin-resistant strains from the patients' lesions and from the noses of the nursing staff is particularly striking. It lends further support to the theory that the nasal mucosa of members of a hospital community acts as a reservoir from which staphylococci are distributed, directly or indirectly, to new entrants into the community, whether they be patients or staff. In this hospital there is a preponderance of penicillin-resistant strains in the noses of the staff, and this is reflected in the large number of wound infections with these strains.

The large numbers of carriers of one particular type (31b) provide an interesting problem. Presumably, when the nurses first enter the hospital their nasal staphylococcal flora is similar to that of the general community; yet it was found that after a period of residence in the hospital 42 of 200 were carrying type 31b compared with 1 in 200 of the blood donors. It therefore seems that this particular strain can take the place of other staphylococci in the nasal mucosa. Whether this is due to some intrinsic characteristics of the strain which give it an advantage over other strains in competition for biological space, or whether this is a reflection of the fact that there are greater opportunities to acquire the strain from an environment in which it is the predominant staphylococcus, is not yet known.

The streptomycin-sensitivity tests showed no streptomycin-resistant strains among the 195 strains isolated from nasal carriers. Of the 12 streptomycin-resistant strains isolated from patients, 11 came from lesions which had been treated with streptomycin and in which the strains had previously been sensitive. The 12th strain appeared towards the end of the survey as a cross-infecting organism in a clean surgical wound in a patient who had received no streptomycin. It belonged to phage type 31b and was also penicillin-resistant. Its appearance in the hospital is disquieting.

It is concluded that there is not at present a high proportion of penicillin-resistant staphylococci in the general population of Sydney. However, in a hospital community where there has been opportunity for the selection and dissemination of resistant strains, a reservoir of such strains exists among staff and patients and constitutes the source of infection of new entrants into this community.

SUMMARY

Of 228 strains of *Staph. pyogenes* isolated from 196 patients in a general hospital 107 (47%) isolated from 104 patients were penicillin-sensitive, and 121 (53%) from 92 patients were penicillin-resistant; 31 (84·5%) were streptomycin-sensitive, and 12 (5 streptomycin-resistant.

Phage typing of the strains showed that dominant phage types occurred among the sensitive strains, but among the penicillin strains 75% belonged to five phage types, with predominating.

Analysis of case-records of patients yielding p resistant staphylococci showed only 8 cases of staphylococcal infection in which infection occ certainty outside the hospital community; 8 were considered to have been cross-infected hospital. In 4 cases conversion to penicillin r occurred while in hospital. Most of the cases o infection were those of clean surgical wounds, evidence indicates that they were infected with already penicillin-resistant *at the time of entry* wound.

Surveys of the nasal carrier-rate of penicillin *Staph. pyogenes* in 200 members of the hosp and in an unselected group of 200 blood a carrier-rate of 32% in the hospital staff c with 4% in the blood donors. A close was found between the distribution of phag present in the noses of the staff and in the l patients cross-infected in hospital.

We are indebted to Mr. G. Barr and Miss V. Sfe technical assistance, and to Mr. R. G. H. Barbour typing some of the strains.

ANÆSTHETIC REGISTRAR, ROYAL ABERDEEN HOSPITAL
CHILDREN

SOME nine months ago the attention of one of us (was drawn to the work of Bovet et al. (1947) and Oostende (1947), and more recently to that o et al. (1949), on tri-(diethylamino-ethoxy) triethiodide ('Flaxedil'), and it was decided t purely clinical investigation of this drug in man its value as a curarising agent.

The pharmacology of flaxedil has been investigated by the above workers, and it h established that it acts at the myoneural jun interfering with the chemical mediator and thus its action in a way very similar to that of *d*-tub chloride; and, as in the case of that agent, i are easily and rapidly reversed by the anti-cholin eserine and neostigmine. It is also suggested t less liable to facilitate the release of histamin have less effect on autonomic ganglia. Chemic miscible with soluble thiopentone, a debatable ad

METHOD

We decided to standardise our anæsthetic t as far as possible, and we used as prem and scopolamine or omnopon and atropine ording to body-weight, followed by soluble and nitrous oxide and oxygen. always trying anæsthesia in either deep 1st or light 2nd at a level where well-marked tone of the nusculature would still be present. In ntubated all the patients with an oral Magill ted with a 'Nupercaine' paste to allow of erated at this light plane of anæsthesia.

dose of flaxedil just as the surgeon reached um, and additional doses when required, to give the last dose at least 30 minutes nd of the operation, because otherwise the ld have an inefficient peripheral respiratory and therefore be unsafe to send back to toperative ward care. In such circumstances ave given neostigmine and atropine; but 1949) and Clutton-Brock (1949) suggest that f these drugs is not without its dangers and oided as a routine.

our dosage was too low, having been based res of the French workers, who were using n normal adult weighing 10 st. On investigaared that the French surgeons were satisfied e of relaxation which in this country would be inadequate, and the anæsthetic used was lane of anæsthesia much deeper than we were ier itself has a curare-like action; thus the axedil 40 mg. used by the French workers considerably reinforced by ether.

0 patients 60 were children and 20 adults. about 12 adults, underwent laparotomy, most ainder undergoing intrathoracic procedures, eumonectomy and lobectomy; 1 underwent perineal excision of the rectum. All the cases led on the standard Nosworthy charts, and had we any cause for anxiety either during or postoperatively, except for 2 children early es who developed a lobar collapse, which in f further experience we feel might have been late exhibition of flaxedil and return to the some intercostal paralysis still present. No o was returned to the ward with full return tal activity developed any chest complication, gures are too small for this to be statistically .

RESULTS

lings were as follows:

xedil 120 mg. gave comparable clinical effects btained with *d*-tubocurarine chloride 15 mg.

axation began 60–90 seconds after intravenous of flaxedil, reached its peak in 120 seconds, for 20–25 minutes, and wore off gradually.

ase was satisfactory abdominal relaxation without some intercostal paralysis. Good was achieved with some diaphragmatic till present.

re was no fall in blood-pressure; on the during surgical stimulus it often rose, conhe light plane of anæsthesia.

ere was no clinical evidence of excessive release ine, if a frequently occurring pallor could be d to the light anæsthesia.

e gut appeared normal during operation—there ollapse and no distension.

venous thromboses were noted.

abnormal constituents were found in the urine.

stoperative sickness was minimal, but sedation ired earlier because of the rapid recovery from plane of anæsthesia.

CONCLUSION

xedil we have a synthetic curarising agent seems to be devoid of undesirable side-actions. Its effects can be easily and rapidly reversed by neostigmine. It can be used in long operations; we have given 400 mg. in a long difficult thoracotomy without ill effect.

A word of warning is essential. As with all agents which cause peripheral respiratory paralysis of any degree, the anæsthetist must be skilled in the care of the apnœic patient. There is no doubt that flaxedil warrants further trial and, if it fulfils its early promise, may well find a permanent place in anæsthetic practice.

HYALURONIDASE IN PÆDIATRIC THERAPY

WILFRID GAISFORD
M.D. Lond., F.R.C.P.
PROFESSOR OF CHILD HEALTH, UNIVERSITY
OF MANCHESTER

D. G. EVANS
D.Sc., Ph.D. Manc.
READER IN CHEMICAL BACTERIOLOGY, UNIVERSITY
OF MANCHESTER

FOLLOWING the reports of Hechter et al. (1947) and Schwartzman et al. (1948) on the potential therapeutic value in pædiatrics of solutions of hyaluronidase, we have used the enzyme, together with subcutaneous infusions of saline and glucose or plasma and glucose. in 39 infants with varying degrees of dehydration.

Our results amply confirm that this is a harmless procedure which greatly enhances both the amount of fluid that can be injected and the rate at which it is absorbed. Its value in the rehydration of infants with gastro-enteritis, in allowing almost immediate operation in infants with pyloric stenosis who are dehydrated, in the treatment of such conditions as severe inanition fever in the newborn, and in increasing the protein and fluid intake in premature babies is undeniable. In addition, the absorption of even large quantities of subcutaneous fluid is comparatively painless because of the lowered tension resulting from the hyaluronidase.

METHOD OF PREPARATION

Our source of hyaluronidase was bovine semen. This was diluted with an equal quantity of distilled water, frozen for twenty-four hours, then thawed and centrifuged. The supernatant fluid was seitz-filtered and freeze-dried. This method allows maximal enzyme extraction and ensures stability for a long time (Swyer 1947).

The hyaluronidase was put up in 1 mg. doses in sealed ampoules of 1·5 ml. volume. Immediately before use an ampoule was opened and 1 ml. of distilled water added to the powdered freeze-dried hyaluronidase in the bottom of the ampoule, solution being instantaneous. The contents of one ampoule were used for each case. We feel that because of the possible loss of potency when the enzyme has been stored in solution, the use of freshly dissolved hyaluronidase is an important factor and contributed greatly to the satisfactory results we obtained.

METHODS OF TESTING

Before being used clinically the preparation was tested for "spreading" activity, allergic effects, and toxicity.

The "spreading" factor was tested by intradermal injection of decreasing doses into the depilated skin of guineapigs. The bleb produced by 0·02 mg. of hyaluronidase in 0·2 ml. of saline solution completely disappeared in less than two minutes, while 0·001 mg. was absorbed in less than ten minutes. The volume of saline solution which could be absorbed, together with the rate of absorption, was investigated in rabbits, varying amounts of hyaluronidase being used to obtain a standard for clinical work. It was then decided to use 1 mg. as this standard in our clinical trials.

To exclude the possibility of the development of hypersensitivity, six guineapigs were injected subcutaneously with 0·01 mg. in 0·2 ml. of saline solution. Fourteen days later 2 mg. in 0·5 ml. of saline solution was injected intravenously into each guineapig. No reactions occurred, either immediately or within the following fourteen days, in any of the animals. Tests for toxicity were made with intravenous injections into mice and guineapigs and showed that doses equivalent to 250 mg. per kg. of body-weight in mice and 20 mg. per kg. in guineapigs produced no toxic manifestations.

METHODS OF ADMINISTRATION

Schwartzman et al. injected the hyaluronidase first and followed this with saline solution—i.e., the needle containing saline solution was inserted into the middle of an area infiltrated with hyaluronidase. On occasions a saline drip was continued for as long as five days. The outer aspect of the thigh was the site used.

After trying this method (both with subcutaneously and intradermally injected hyaluronidase), and also trying adding the hyaluronidase first to the total solution to be given, our best results were finally obtained when the hyaluronidase (1 mg. freshly dissolved in 1 ml. of distilled water) was injected through the rubber tubing about an inch from the needle as soon as the flow of fluid began. An ordinary two-way subcutaneous infusion set was used and the fluid run in by gravity in every case except in one premature infant for whom speed was essential and the fluid was injected from a 20 ml. syringe. Ordinary-gauge hypodermic needles were used, and the bottle containing the solution was raised to about 3 feet above the level of the cot mattress.

Because it is important that a sick infant should be disturbed as little as possible and prolonged exposure is therefore to be avoided, all injections were made without moving the infants from their cots and at the quickest possible speed, the average time taken (excluding the initial cases, when various methods were being tried) was thirty minutes for an average of 200 ml. of fluid (half-normal saline solution and 5% dextrose).

The ideal site for subcutaneous infusions in an infant is the anterior abdominal wall. One needle is inserted on each side of, and about 1 inch from, the umbilicus and directed laterally. Absorption is maximal and most rapid at this site, the area is clean and away from napkin contamination more than when the thigh is used, and minimal disturbance of the infant is required. It also seems to cause the least discomfort to the infant.

When we started this investigation "control" trials were made. The fluid was allowed to run in on each side till two weals, each containing about 10 ml., were raised. One tube was then clipped and hyaluronidase injected into the other. Two striking things were repeatedly noticed: firstly, the rate of flow, as seen in the dropper, continued as fast as if both sides were being used, and, secondly, the infants rapidly stopped crying. Another interesting observation was that, on removing the needle from the side which had hyaluronidase injected, no collodion was necessary to stop leakage through the needle pucture—there was no leakage.

During the injections the infants could usually be kept quiet by being given a sweetened teat to suck (or a milk feed if the general condition allowed).

One problem which arose was whether abdominal wall, the site of election, could infants in whom abdominal operation wa within a matter of hours, and whether, if it would be any risk of hæmorrhage or of inf found that it was safe to inject at this site hours before a Rammstedt's operation was that there was no abnormal hæmorrhage, sepsis followed. In one case, where mild p present on the anterior abdominal wall, the given into the thigh. However, in view of of Sannella (1940) that hyaluronidase did an experimentally induced infection with *aureus* in rabbits and the explanation of (1947) that hyaluronidase diffuses round and a fibrin barrier—i.e., takes the line of least the abdominal wall might have been used

In the hope of providing easily abs plasma infusions were next tried. Dried reconstituted with 5% dextrose and injected Because of the increased viscosity the flow slower; hence larger needles were nece operation were to be completed within th minutes. Absorption similarly was slower comparable rate of absorption, twice the hyaluronidase had to be used—i.e., 1 mg. into The final disappearance of injected plasma delayed, as compared with saline solution for as long as forty-eight hours—and there round the site of injection a wide area of which persisted for a similar length of time. to be quite harmless.

The possibility that whole blood might when given subcutaneously is worthy of Schwartzman (1949) used it in 3 cases and absorption of 100 ml. in three hours at a drops a minute. This would seem to be of only in those infants in whom no veins are the usual intravenous technique and in down on the vein would otherwise have to

Extension of the technique to include administered drugs which are in large volume —e.g., serum in measles prophylaxis whe globulin is not available, and chemothe high blood levels are indicated and oral is precluded by vomiting. Pain will diminished and absorption ensured.

The time taken to run in the 200–250 ml. which was the average volume used, was fair and varied only with the calibre of the needle height of the fluid. It did not vary with the dehydration, but the time of absorption was shorter in the more dehydrated infants.

Repeated infusions may be given as have found it advisable to change the site of in such circumstances and to inject fresh each occasion. Undoubtedly the effect wears for, though absorption will still be better than any hyaluronidase when a second infusion is same area some hours after the first there is a able falling off in the volume which can be in the rate of absorption.

RESULTS

Clinical results are comparable with those intravenous injections of saline solution, though ment is not so rapid. Rehydration can effected adequately and circulation successfully in collapsed dehydrated infants.

So far our experience, since first using hya in January last, has been limited to 10 cases stenosis, 23 of gastro-enteritis, 3 of prematur influenzal meningitis, 1 of duodenal stenosis; imperforate anus.

ıfants with pyloric stenosis and 2 of the 3 nfants did well, as did the 1 with meningitis e necessity for gavage was obviated by the The newborn infant with duodenal stenosis ed, and his progress was undoubtedly helped ıluronidase. He received infusions of both saline solution : 150 ml. of plasma with 5% s absorbed in four or five hours, and a subsetion of 200 ml. of saline solution and dextrose bsorbed in two and a half hours. After he infant with the imperforate anus received hour 270 ml. which was absorbed in three the 23 gastro-enteritis infants 5 died. evealed *no evidence of any ill effects which* cribed to hyaluronidase, and in 1 case all the uid which had been given only twelve hours h was found to have been absorbed.

es two or more separate infusions were given, s into the original site six hours after the first nd without any further hyaluronidase. The ıts were given their second injection into the ne infant with severe gastro-enteritis had four two of saline solution and two of plasma, and ood recovery.

nabled to ensure the absorption of 60 ml. of tion or of plasma and glucose in a premature ghing $2^1/_2$ lb. with minimal disturbance of the a great advantage, and, since hyaluronidase be completely non-toxic, it is certainly worth ed trial.

e have been using hyaluronidase, preoperative us therapy in dehydrated infants with pyloric as been practically abandoned, and the number nous injections in infants with gastro-enteritis considerably reduced.

bviously desirable that a standard preparation onidase should be established in terms of which cy of different preparations may be assessed accurg., by the method of Swyer and Emmens (1947).

cere thanks are due to Dr. Swyer for providing the dase.

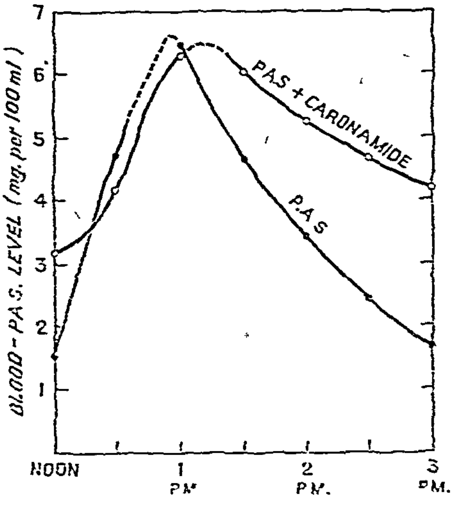
e Departments of Tuberculosis and of Therapeutics, dinburgh University and Southfield Sanatorium

GH *p*-aminosalicylic acid (P.A.S.) was first synby Seidel and Bittner in 1902, it was not until at attention was focused on it as a therapeutic ı tuberculosis. Lehmann (1946), in his search for unds with a bacteriostatic effect on the tubercle , tested in vitro more than fifty derivatives of acid and found P.A.S. the most active. He also its effects in experimentally infected animals and d favourable clinical results in man. Since this l work was published, an increasing number of on the clinical effects of P.A.S. and on its use in nental tuberculosis have been published. These ecently been reviewed by Nagley and Logg (1949).



Effect of caronamide on P.A.S. blood-levels in patient receiving 3 g. P.A.S. 3-hourly from 9 a.m. to 9 p.m.

P.A.S. is a white crystalline powder, and solutions of its sodium salt are obtained by means of sodium bicarbonate, carbonate, or hydroxide. Given by mouth, P.A.S. is rapidly absorbed and rapidly excreted; therefore frequent doses are needed to maintain adequate blood-P.A.S. levels. Typical blood-P.A.S. levels in a patient receiving 15 g. daily in three-hourly divided doses are shown in the accompanying figure. It will be seen that P.A.S. is rapidly absorbed, the blood-P.A.S. level being highest towards the end of the first hour and falling quickly thereafter until at the end of the third hour it has almost disappeared. Lehmann (1946) described a similar type of blood-P.A.S. curve and stated that, when all the blood-P.A.S. levels are followed, the concentration index (ratio of urine-P.A.S. level to blood-P.A.S. level) is about 100 to 1. He added that, for this reason, P.A.S. was probably not reabsorbed in the tubules of the kidney. Alin and Difs (1947) emphasised that there was great individual variation in the rate of absorption and excretion of P.A.S., and that the rate could be influenced by various methods of coating the capsules in which P.A.S. was given.

Way et al. (1948), in their report on the metabolism of P.A.S., to which we had access only at a late stage of our investigation, described a plasma-P.A.S. level similar to ours. Much the highest concentration of P.A.S. is attained in the kidney, the lungs and liver showing the next highest concentrations (Alin and Helander 1948, Way et al. 1948). The binding of P.A.S. by plasma-proteins has already been noted by Way et al. (1948). P.A.S. is absorbed almost completely from the gastro-intestinal tract, and within four hours about 80% of it has been excreted into the urine.

PRESENT INVESTIGATION

The rapidity with which P.A.S. is excreted in the urine made it probable that the renal tubules as well as the glomeruli played a part in the excretory process. For that reason it was considered worth while to compare the plasma-clearance rate with that of a substance which is dealt with purely by glomerular filtration—e.g., inulin—and, if the supposition regarding tubular excretion proved correct, to ascertain whether that part of the process could be inhibited.

'Caronamide' inhibits the tubular excretion of penicillin, diodone, and phenolsulphonephthalein (Beyer 1947). It has been shown further (Beyer et al. 1947) that caronamide has no effect on the glomerular filtration of inulin or on the tubular reabsorption of threshold substances such as glucose. We therefore decided to investigate the action of caronamide in patients receiving P.A.S. for pulmonary tuberculosis. In all cases P.A.S. was given in a daily dose of 15 g. of the sodium salt, 3 g. being given every three hours from 9 A.M. till 9 P.M. Plasma-clearance values, based on the formula $\frac{UV}{P}$, were determined during the hour from 1 to 2 P.M.

TABLE I—EFFECT OF CARONAMIDE ON P.A.S. CLEARANCE AND BLOOD-P.A.S. LEVEL

Case no.	Inulin clearance (ml./min.)	P.A.S. clearance (ml./min.)	P.A.S. clearance after caronamide (ml./min.)	Blood-P.A.S. level at 1.30 A.M. (mg. per 100 ml.)	Blood-P.A.S. level at 1.30 P.M. after caronamide (mg. per 100 ml.)
1	132	185	102	3·5	5·5
2	147·6	181	65	3·6	7·4
3	102	115	46	4·7	7·7
4	125	158	100	3·4	5·3
5	130	194	58	3·4	7·0
6	103	153	58	2·4	5·6
7	144	168	72	4·7	6·0

Caronamide was then given in a dose of 4 g. every four hours. *After twenty-four hours, to allow equilibration,* the clearance of P.A.S. was again determined.

Estimations of P.A.S. in urine and plasma were made by the method of Newhouse and Klyne (1949). Using this method it was found that caronamide alone or in conjunction with P.A.S. had no effect on the intensity of the colour reaction.

RESULTS

The results obtained in seven cases are summarised in *table* I. *It will be seen that* in each case the renal clearance of P.A.S. exceeded the inulin clearance, and was reduced by caronamide to a value much below the figure for inulin. At the same time the blood-P.A.S. level rose. The cumulative effect of caronamide on blood-P.A.S. levels is clearly shown in the figure.

We thought that this somewhat unexpected result might be due to the fact that, as with diodone, a proportion of the P.A.S. in the blood is bound to protein and is *not available for glomerular filtration.* The distribution of P.A.S. in plasma and erythrocytes was therefore studied. From plasma a protein-free filtrate was obtained by ultrafiltration through a 'Cellophane' membrane under a positive pressure of 60 inches of water. We confirmed that there was no loss of P.A.S. from plasma allowed to stand at room temperature for the period of filtration (usually overnight). The results of several experiments, summarised in *table* II, show that about two-thirds of the blood-P.A.S. is in the plasma, and *about a third of that is bound to protein.*

TABLE II—DISTRIBUTION OF P.A.S. IN BLOOD

Case no. ..	3		4		5		6	
P.A.S. (*mg. per 100 ml.*) *in :*								
Whole blood	4·0	8·5	3·7	4·7	3·4	3·7	2·3	3·3
Plasma	5·6	12·6	4·1	5·6	5·1	4·6	3·3	4·4
Erythrocytes	2·6	4·9	3·3	3·75	1·7	2·8	1·3	2·4
Plasma ultra-filtrate ..	3·25	9·4	2·7	3·4	3·2	3·0	2·5	3·2
Packed cell volume (%) ..	53	..	48	..	50	..	53	..
Plasma-P.A.S. bound to protein (%)	42	25	34	39	37	35	24	27
Proportion of blood-P.A.S. present in plasma (%) ..	66	70	58	62	75	62	68	63

If glomerular filtration and tubular excretion were the only two processes by which the kidney deals with circulating P.A.S., it might be expected that caronamide, by inhibiting tubular excretion, would reduce the clearance value of P.A.S. to slightly less than that of inulin. In five of the seven cases, however, the reduction in the P.A.S. clearance was much greater than could be explained on this basis; therefore it is necessary to postulate an additional mechanism. We suggest that the renal tubules, besides excreting P.A.S., *reabsorb it,* the reabsorption not being apparent until excretion is inhibited by caronamide.

Further studies are being made to investigate the effect of giving caronamide in conjunction with P.A.S. for longer periods than was done in these initial experiments.

SUMMARY

p-Aminosalicylic acid given by mouth is rapid and rapidly excreted in the urine, partly by filtration, partly via the tubules.

Tubular excretion can be inhibited by c but the resultant rate of excretion, com inulin-clearance values, is considerably less t be expected from simple glomerular filtration therefore, the renal tubules, besides reabsorb it.

It is possible by giving caronamide in c with P.A.S. to obtain higher blood-P.A.S. levels be obtained by giving P.A.S. alone.

The possible therapeutic application of th is being investigated.

We are grateful to Dr. J. S. Robson and D Ferguson for determining the inulin clearances, t Stewart for much advice and helpful criticism, and Hay for technical assistance.

EFFECT OF NORADRENALINE ON HUMAN CIRCULATION

H. J. C. SWAN
M.B. Lond., M.R.C.P.
From the Sherrington School of Physiology, St. T
Hospital, London

NORADRENALINE—(amino methyl) 3, 4, d benzyl alcohol—differs from adrenaline in l methyl grouping on the amino nitrogen of the The properties of the synthetic *dl* form were first in 1910 by Barger and Dale, who recognised its mimetic action and emphasised its close relationship to adrenaline. Its physiological was probably first postulated by Bacq (19 thought it might be the sympathin E of C Rosenblueth (1933). This possibility was also likely by Greer et al. (1938), but subsequent saw difficulties in accepting noradrenaline as the *thetic mediator,* since in certain respects did not have the known properties of liver (sympathin E).

In 1946 interest was aroused afresh in this su for von Euler (1946) demonstrated the pre *l*-noradrenaline in mammalian tissue, and the of the isomers of the synthetic *substance* by Taint (1948) opened an extensive and widespread inves into its *physiological and pharmacological* imp Holton (1949) has estimated that 50–80% of the substance extracted from pheochrom noradrenaline, and Auerbach and Angell (194 shown that the *U.S.P.* standard adrenaline adrenal *medulla of cattle)* contains *10–18%* of nor line. Goldenberg et al. (1949) have reported agreement with the findings of both these Bulbring and Burn (1949) have demonstrated the cat the pressor substance liberated from the medulla on *splanchnic stimulation* is *a* mi adrenaline and noradrenaline.

Noradrenaline is therefore a substance *of* con physiological interest, and *experiments have* be to demonstrate its action in man by Goldenber (1948) and *independently* by Barcroft and

d diastolic pressure levels well above basal
he bradycardia is also a pronounced feature.
hat in the presence of a bradycardia there is
iastolic pressure suggests an increase in total
resistance, and Goldenberg et al. (1948)
n by an indirect estimation that noradrenaline
h an effect, in contradistinction to adrenaline,
ses a fall in total peripheral resistance. These
ave also shown that noradrenaline usually
fall in cardiac output or sometimes leaves it
l. The pressor effect therefore depends mainly
e in resistance in the peripheral vascular bed.
nge in peripheral resistance is probably not
hroughout the vascular bed, but from fig. 1
seen that the effect on calf blood-flow, which is principally through skeletal muscle, is to diminish the flow. Because the flow varies directly with inflow pressure and indirectly in relation to the resistance of the vascular bed, one can say there is an active vasoconstriction. This phenomenon has been investigated by Barcroft and Konzett (1949b) who though they found little change in forearm flow on intravenous infusion showed that intra-arterial infusions into the femoral artery caused a vasoconstriction in the calf, and concluded that noradrenaline acts directly on the blood-vessels in the muscle.

The effect of infusion of noradrenaline on the flow of blood through the hand, which flow is chiefly through skin, is to produce a definite vasoconstriction, which is maintained during the period of infusion. This vasoconstriction is a local action on the skin vessels, for it occurs when the vasoconstrictor fibres are sectioned, as in persons who have undergone sympathectomy. The constrictor effect on the skin does not seem to be so great as that caused by equal doses of adrenaline—an observation which is reflected in the degree of pallor which the two drugs may produce. However, as with adrenaline, there is a similar dilatation in the hand after the local effects of the substance have worn off.

BRADYCARDIA

An attempt was next made to elucidate the bradycardia resulting from noradrenaline infusions. The effect was probably reflex, since in the isolated mammalian heart noradrenaline causes tachycardia. Goldenberg et al. (1948) mentioned that the bradycardia was abolished by atropine; hence it seems to be a vagal reflex. Fig. 2 shows the effect of the infusion of 0·005 mg. noradrenaline per minute before and after, the intravenous injection of 1·3 mg. of atropine, and fig. 3 shows the effect of the same dose on another person after the intravenous injection of 2 mg. of atropine. Both these persons showed a more pronounced pressor response than usual, for their response to 0 005 mg. was similar to that produced by 0·02 mg. in fig. 1. It will be seen at once that the bradycardia has not been abolished, but it is almost certain that neither person was fully atropinised. In other persons the bradycardia was abolished.

The potentiating effect on the blood-pressure response is remarkable, however, and emphasises the importance of the vagal reflexes in the regulation of blood-pressure. By analogy, very small doses of pressor substances circulating in a person with relatively insensitive vasomotor regulation would produce a much higher blood-pressure than the same amount of substance in a person with a brisk vagal response. Goldenberg et al. (1948) recognised the similarity of the pressor effect of

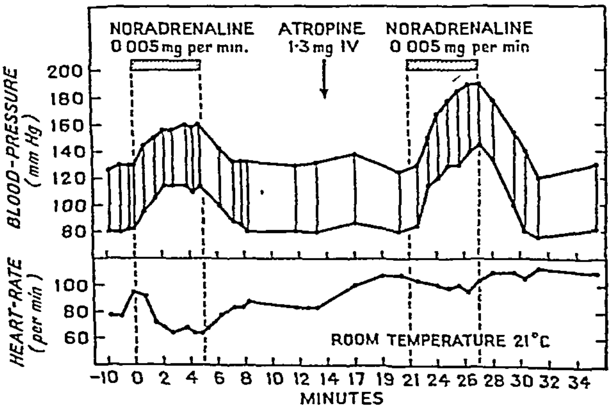

Fig. 2—Blood-pressure and pulse-rate of hypertensive person given noradrenaline 0·005 mg. per min. before and after intravenous atropine 1·3 mg.

noradrenaline to essential hypertension. Perhaps the sensitivity of the vasomotor reflex may also be a factor worthy of interest in hypertensives who have an unusually rapid heart-rate.

SUBJECTIVE SYMPTOMS

Few persons noted disturbing subjective symptoms. If they complained, the common story was of an "uneasy awareness." On questioning, they usually said they felt compelled to breathe more deeply, and sometimes they noted that their heart's action seemed slower and more forceful. Some of the persons in whom a well-marked rise of blood-pressure was produced complained of a transient headache.

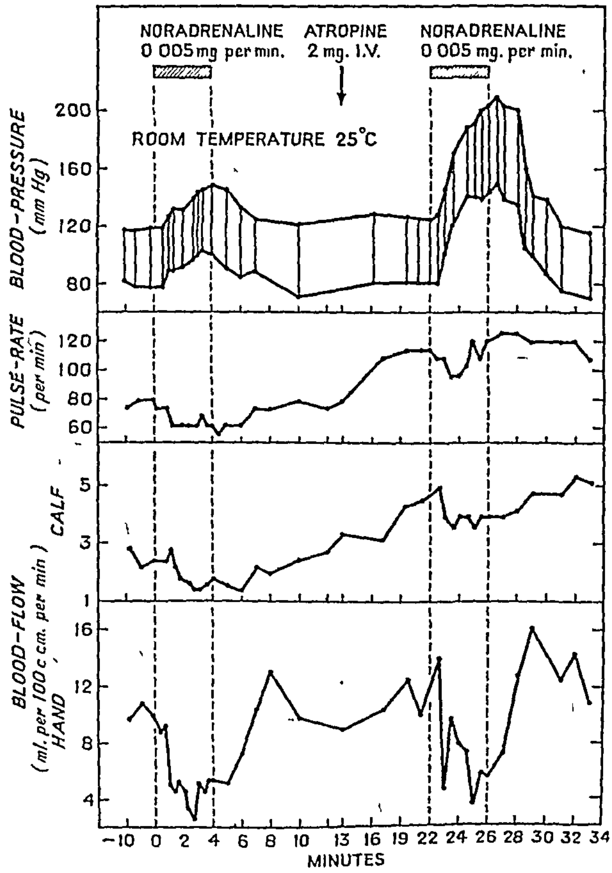

Fig. 3—Blood-pressure, pulse-rate, and blood-flow in hand and calf of another person given noradrenaline 0·005 mg. per min. before and after intravenous atropine 2 mg.

SUMMARY

Noradrenaline, a substance which has been shown to occur in man, has been administered to normal people.

The main effect was a peripheral vasoconstriction, which led to a rise in both systolic and diastolic blood-pressures.

A bradycardia developed which was probably reflex in origin. In the absence of such a bradycardia the effect of noradrenaline was potentiated.

The *l*-noradrenaline hydrochloride was part of the sample made available to Prof. Henry Barcroft by Dr. M. L. Tainter. My grateful thanks are due to the subjects of the experiment. It gives me much pleasure to acknowledge the kindly advice and assistance I received from Professor Barcroft and also from Dr. H. Konzett, who was associated with Professor Barcroft in much of the original work done on the subject in this country. Mr. J. Dalrymple gave efficient technical assistance.

FACIAL PALSY AND POLIO

THOMAS STAPLETON
M.A., B.M. Oxfd, M.R.C.P., D.C.H.
From the Department of Child Health, University of

THE ætiology of the facial palsy of lo neurone type, sometimes known as Bell's obscure. Local chilling has been regarded a tributory factor, and an association with the herpes zoster has occasionally been noted however, no satisfactory explanation is found

Walshe (1947) has drawn attention to the incidence, cases tending to occur in groups in autumn and early spring.

The possibility of an association between facial palsy and poliomyelitis has been previously (Lavergne et al. 1932, Kissel 1938, 1944). Lavergne et al. (1932) were able to find of over 80 cases of isolated facial palsy which attributed to this infection.

In the Mauritius outbreak (Seddon et al. 1946) cases (2·5%) had involvement of the medulla, but of 500 cases (0·6%) had any permanent facial though the period of observation was not long assess the ultimate degree of recovery.

In the London epidemic of 1947 a high proportion with cranial-nerve involvement was noted (Ke of 66 cases, 19 had a cranial-nerve lesion and 5 of facial paralysis.

In the Malta outbreak (Agius et al. 1945) there high incidence of facial paralysis; of 426 cases myelitis, facial paralysis (which was always occurred in 47 (11%), and the important obse made that 29 of these showed no other abnormality months after the epidemic was over 10 cases still paralysis.

Kissel (1938) reported an outbreak in a villa there were 7 cases of facial paralysis, unaccom other paresis in 3 and associated with a 6th ne on the same side as the facial lesion in 4. There the 4 cases of poliomyelitis with ascending paralysis, 3 were fatal; 1 fatal case with bulbar paralysis paralysis; and a final case with an isolated f All the cases occurred within one month.

Wyllie (1944) observed a family in which 2 m facial palsy, 2 had "influenzal symptoms," 1 had a and 1 had clear-cut poliomyelitis with paralysis a He thought that the first case of facial paralysis to poliomyelitis, and resulted in paralytic and disease in the other members of the family.

From these various observations it seems not un able to suppose that some cases of so-called Bell are really due to poliomyelitis. A small series of facial palsy which occurred about the time outbreak of poliomyelitis is recorded here.

PRESENT SERIES

During 1948, 22 cases of poliomyelitis were in Sheffield; in the same year 8 cases of facial palsy of lower motor neurone type of unknown unaccompanied by other paresis attended the patient department of the Children's Hospital,

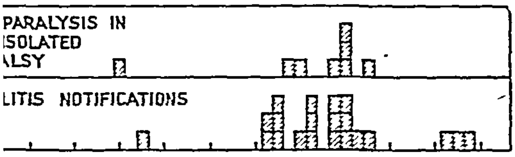
on arises whether there was a relation between oups of cases. The peak of occurrence of the ions appears to coincide (see figure), and it is at the grouping of the cases of facial palsy was

I am indebted to Mr. G. H. Jowett for the tatistical comment :

f isolated facial palsy were uniformly distributed the year, the second moment of the week number currence of 8 cases would have an expected value d a standard error of 71·3. The observed second 43·5 which differs from 197·2 by more than twice fore it may be concluded that the hypothesis of stribution is unacceptable, the dispersion of the too small to be a likely chance finding.

y *the following 5 case-histories illustrate an* gradation between frank poliomyelitis and ial palsy.

Poliomyelitis with initial facial paralysis and later paralysis.—A girl aged 2 years 5 months developed espiratory infection on Sept. 26, 1948 ; during the week she vomited occasionally and had slight Oct. 2 she developed a left facial palsy. Admitted on the 3rd, she was apathetic and drowsy with r (temp. 100·2°F in the axilla). The only neuro-normality found that day was a left facial palsy motor-neurone type. Lumbar puncture next day erebrospinal fluid containing 80 mononuclear cells , with protein 40 mg., chlorides 720 mg., and sugar r 100 ml. On Oct. 5 she developed early paralysis ntercostal muscles. She was transferred to the Hospital and died on Oct. 6.



. *Poliomyelitis with facial paralysis and nystagmus.*—d 1 year 6 months became unwell on Aug. 31, 1948. 3 she developed a right facial palsy. On the 4th ne slightly febrile, the fever persisting until her to hospital on the 7th. The abnormal neurological hen were meningism, nystagmus, and a right facial he cerebrospinal fluid contained 90 mononuclear cmm., with protein 30 mg., chloride 750 mg., and mg. per 100 ml. On Sept. 8 no ocular abnormality d. She developed no further paralysis. The facial still complete 36 weeks later.

. *Facial paralysis and normal cerebrospinal fluid.*—alysis this is considered as a case of facial paralysis

aged 2 years 8 months became slightly unwell on 1948. On Oct. 2 she developed a right facial palsy. her mother noticed that her eyes were "flitting this may have been due to transient nystagmus. seen in the outpatient department on Oct. 4 when neurological abnormality found was the right facial he cerebrospinal fluid contained 7 cells per c.mm.; was less than 10 mg. per 100 ml., with chlorides and sugar 80 mg. Her facial paralysis completely d within 12 weeks.

4. *Facial paralysis with some associated malaise.*—ged 4 years was noticed to be sleepy and tired ; she ed of a little aching behind the right ear ; she was rish. Next day she was found to have a complete cial palsy of lower-motor-neurone type. She was d by an otologist who found no abnormality of the e paralysis was still complete 32 weeks later. The pinal fluid was not examined.

5. *Facial paralysis with no general disturbance.*—ged 5 years was perfectly well, when one morning er noticed that his face was asymmetrical and that difficulty in whistling. He had a right facial palsy which recovered in 11 weeks. The cerebrospinal fluid was not examined.

Of the 8 cases of isolated facial palsy, 6 recovered within 12 weeks. At 32 weeks after the onset, 2 still had paralysis.

The observers in Malta (Agius et al. 1945) attributed their cases of isolated facial palsy to poliomyelitis (1) because of the absence of other causes, (2) because of the presence of the same kind of general disturbance, and (3) because of their occurrence during an epidemic period. The first of these criteria applies to all the cases of isolated facial palsy in the present series, and the last applies to 7 of the 8 cases. Only 4 of the 8 had any associated malaise.

Though there is a suggestion that the cases of facial palsy unaccompanied by other paralysis had a cause in common with the cases of poliomyelitis, this hypothesis is not, of course, proven. The numbers were small : the cases of facial palsy seen in the outpatient department may not have been a true reflection of the incidence ; the notification figures of poliomyelitis, in view of the difficulties in diagnosis, only give an indication of the time of the epidemic ; and the concurrence of the outbreaks was only observed during the one year.

SUMMARY

The simultaneous occurrence of a group of cases of isolated facial palsy and of poliomyelitis is recorded. The possibility that the cases of facial palsy were caused by the virus of poliomyelitis is discussed.

I wish to thank Mr. G. H. Jowett, lecturer in statistics in the University of Sheffield, for the statistical note ; Dr. Llywelyn Roberts, medical officer of health for Sheffield, for the notification figures of poliomyelitis ; and Prof. R. S. Illingworth and Dr. T. Colver for permission to quote their cases.

CURARE WITH GENERAL ANÆSTHESIA FOR FORCEPS DELIVERY

J. D. Bourke
M.B. N.U.I., D.A.
SENIOR RESIDENT ANÆSTHETIST, ROYAL INFIRMARY, EDINBURGH

CURARE as an adjuvant to general anæsthesia ensures a reduction in the quantity of anæsthetic used and therefore a reduction in toxicity. For this reason, as well as for its relaxant power, it has been used in cæsarean section, 100 cases being reported by Whitacre and Fisher[1] and 30 cases by Gray.[2] There was no evidence of curarisation or medullary depression in the infants.

The present investigation into the use of curare in forceps deliveries was instigated by the following case :

A woman, aged 27, with severe pre-eclamptic toxæmia, was admitted to hospital on April 16, 1948. Labour began spontaneously, and the patient was given bromethol rectally (Dewar and Morris[3] technique) to control her restlessness and toxæmia. The fœtus was thought to be dead, since no heart sounds could be heard. After forty-three hours' labour instrumental delivery under general anæsthesia was decided on and, on the presumption that the fœtus was no longer viable, the case was thought suitable for testing curare.

Anæsthesia was induced with nitrous oxide and oxygen. When the patient became unconscious, 10 mg. of *d*-tubocurarine chloride was given intravenously. Ether was then added to the gases, and it was noted that the patient tolerated a rapid rise in concentration of the anæsthetic mixture, an *observation which was confirmed in subsequent cases treated* with curare. The pelvic floor was well relaxed, and delivery was accomplished without episiotomy. The infant took a first breath after 12 seconds; in 10 minutes it was fully resuscitated and cried.

---

[1] Whitacre, R. J., Fisher, A. J. *Anæsthesiology*, 1945, 6, 124.
[2] Gray, T. C. *Brit. med. J.* 1947, i, 444.
[3] Dewar, J. B., Morris, W. I. C. *J. Obstet. Gynæc.* 1947, 54, 417.

After this favourable result in circumstances in which both mother and fœtus were poor risks, an extended trial of curare in forceps cases was instituted.

TECHNIQUE

As premedication, atropine sulphate gr. $^{1}/_{100}$ was given intravenously or intramuscularly to ensure a timely effect. Anæsthesia was induced with nitrous oxide and *oxygen or a small dose of thiopentone (0·25–0·5 g.),* after which the patient was given 10 mg. of *d*-tubocurarine chloride intravenously. The main anæsthetic—cyclopropane, ether, or 'Trilene'—was then administered along with a high concentration of oxygen to prevent hypoxia and medullary depression in the fœtus. Narcosis was maintained at the lightest level until delivery was completed. When a closed-circuit machine was used, the absorption of carbon dioxide was suspended until the cord was tied. Twenty-four mothers, one of whom had twins, were anæsthetised by this technique. Induction was by nitrous oxide in thirteen cases and by thiopentone in eleven.

RESULTS

Anæsthesia

A dose of 10 mg. of *d*-tubocurarine chloride was not exceeded in any of the cases, and it was noted that respiration was never abolished, though its depth was reduced to some slight extent. The size of the abdomen in pregnancy and its restrictive effect on breathing must be borne in mind when giving curare.

The partially curarised patient tolerated a steady quick rise in the concentration of ether.

A smaller amount of general anæsthetic was required; the deep anæsthesia usually requested for relaxation of the pelvic floor was not necessary.

The average *time between induction and delivery* was 17 minutes.

Delivery

Uterine contractions were not affected.

A contraction ring which was present in two cases persisted, and an antispasmodic drug had to be given.

The muscles of the pelvic floor were well relaxed, allowing intravaginal manipulation and making episiotomy a matter of choice rather than necessity.

In the third stage the uterus contracted well, and the placenta was expelled in each case without excessive bleeding or delay.

Infant

Of the 25 infants 16 breathed *immediately,* 7 within 1 minute, and 2 within 2 minutes of delivery. The average time taken by the infant to breathe after delivery was 15 seconds. In the cases induced with thiopentone the average time was 21 seconds, and in those induced with nitrous oxide it was 10 seconds. The average time taken by the infant to cry after delivery was 2 minutes 36 seconds; in the cases induced with thiopentone the average time was 2 minutes 50 seconds, and in those induced with nitrous oxide it was 2 minutes 22 seconds.

CONCLUSION

From these results it seems that, whereas induction with thiopentone shortens the period of unconsciousness of the mother, it lengthens the interval between birth and the start of breathing and crying of the infant. Barbiturates may therefore be inadvisable when prenatal circulatory depression is observed in the fœtus.

The kindly help in this investigation of Prof. J. R. Kellar and his assistants is gratefully acknowledged.

STRANGULATED MESENTERI
OF CÆCUM

J. F. H. BULMAN
F.R.C.S.

MESENTERIC hernia has been fully revi
past ten years: Dolton[1] reviewed 76 ca
Scott[2] reviewed 50 cases; and Hansma
examining the published reports of inter
types, found 38 mesenteric cases, compr
total.

In a brief study of the published case
one in which the cæcum, the lower half
colon, and a corresponding piece of term
all passed through a hole in the base o

ctors are necessary for the formation of a lpos—complete obstruction in the lower part ital canal, and bleeding from some point above ıction. The usual type of hæmatocolpos met ıe to imperfect canalisation of the lower end llerian ducts (usually a so-called imperforate ıd menstruation. The hæmatocolpos described ttributable to trophic (senile) adhesive vaginitis ng from an endometrium stimulated by œstro- apy. No similar case appears to have been

CASE-RECORD

ed woman, aged 68, was admitted to this hospital , 1949, complaining of lower abdominal pain for and vomiting and difficulty in starting micturition s.

History—She had borne four children. Since her at the age of 45 there had been no vaginal bleeding. 10, 1948, she had consulted her doctor because of n the region of her vulva and stress incontinence Local treatment with 'Menopax' ointment and tion of dienœstrol 1 mg. by mouth daily was nd it continued until admission to hospital— ır months. When she was seen as a private patient W. Nankivell, gynæcological consultant, on Oct. 26, pruritus had considerably improved, the cervix atrophic, and operative repair of a cystocele and vas advised.

ıission.—Abdominal palpation revealed a tense elling, situated symmetrically in the abdomen, of the pelvis, and extending upwards to almost etween the symphysis pubis and the umbilicus. ghtly tender and dull on percussion and resembled dder, but after insertion of a urethral catheter it unchanged and only 1 oz. of urine was voided. al examination a cystocele and a rectocele, each as a duck's egg, were found. The vagina ended out 2 in. above the introitus. The lower pole of the cystic swelling was felt by the examining finger, but appeared to be separated from its tip by tough tissue about $^1/_2$ in. thick. Examination with a speculum showed atrophic and stippled vaginal lining characteristic of colpitis senilis. About 2 in. from the introitus the anterior and posterior vaginal walls appeared to be glued together.

Operation (Jan. 15, 1949).—Under intravenous thiopentone anæsthesia, supplemented with nitrous oxide, oxygen-ether inhalation, an Auvard speculum was inserted into the vagina, whose anterior and posterior walls were separated from each other, first with a probe and then with the finger, which soon penetrated into a large cavity, representing the greatly distended upper part of the vagina. The adhesion between the anterior and posterior vaginal walls was quite firm and required some pressure to break it down. The cavity so entered contained about 300 ml. of tarry fluid blood, which escaped under tension. It was now possible to inspect the cervix uteri. This was flat and atrophic and showed no sign of a growth. Bimanual examination revealed that the cystic swelling had disappeared and that the uterus was small and freely movable. The uterine appendages were not palpable. The speculum was reinserted, and a cuff-like oozing area $^1/_2$ in. wide was seen to encircle the vaginal wall, corresponding to the adhesion which had been broken down. To exclude carcinoma of the body of the uterus and to obtain some mucosa for histological examination, a diagnostic curettage was done after dilatation of the cervical canal to Hegar 7. However, no mucosa was obtained with the curette. The length of the uterine cavity was 6 cm. The vagina was lightly packed with gauze.

Postoperative Course.—The vaginal pack was removed after twenty-four hours. Discharge of some stale fluid blood continued for four days, and the patient left hospital on Jan. 20, five days after evacuation of the hæmatocolpos.

Follow-up.—The patient was seen again on Jan. 26, when she felt perfectly well and there was no vaginal discharge. There was some evidence of colpitis senilis, but the cuff-like eroded area described above was covered with epithelium. The upper third of the vagina, which had only recently been found greatly distended, had shrunk to the width of the lower two-thirds. The cervix was easily accessible, flat, and atrophic. The uterus was small.

On Feb. 10 the findings were unchanged. The patient was advised not to take any tablets, and to report to her doctor at four-week intervals.

DISCUSSION

Source of Blood

A bleeding growth of either the cervix or the body of the uterus was excluded by inspection and curettage respectively, and there was no evidence of a feminising mesenchymoma (e.g., granulosa-cell tumour) of the ovary. There can thus be little doubt that the blood of this hæmatocolpos originated from the endometrium stimulated by the œstrogen which had been administered. The patient received dienœstrol 1 mg. by mouth daily for four months, as well as an unspecified amount of stilbœstrol by inunction (1 g. of the ointment used contains 1 mg. of stilbœstrol).

The relative potency of dienœstrol has recently been the subject of investigations. According to Barnes (1942), dienœstrol is ten times more effective than stilbœstrol in suppressing lactation, and Emmens (1938) states that it is four times as active as stilbœstrol if given by mouth to mice. On the other hand, Kemp and Pedersen-Bjergaard (1943), Bishop et al. (1948), and Harmer and Broom (1948) assess the relative potency of dienœstrol at a half, a quarter, and two-thirds of that of stilbœstrol respectively.

Continuous administration of œstrogens to a woman with amenorrhœa is liable to produce endometrial hæmorrhage, which, in Bishop's (1947) nomenclature, is termed "threshold bleeding."

Apart from alarm and anxiety, if the patient has not been warned of the possibility of a hæmorrhage, little harm is usually done by the bleeding, and, in our present state of knowledge, the danger of carcinogenic action of œstrogens is remote. However, the present case shows that a pathological condition may be produced by uninterrupted and uncontrolled administration of œstrogens. "It is in the treatment of the menopause that overdosage is so often practised" (Bishop 1947).

Obstruction

The formation of vaginal adhesions in the course of colpitis senilis is not rare. Opposing areas of the vaginal wall, denuded of epithelium and inflamed, become adherent to one another, bands are formed, and in extreme cases the cervix is completely shut off from below.

Adhesions may develop at any level but more often affect the junction of the upper and middle thirds of the vagina, where they were present in this patient. At this level, too, pericolpitic fibrosis and shrinkage may develop, constituting Labhardt's (1924) Kraurosis fornicis vaginæ, though on rare occasions similar changes have been found lower down, constituting Halban's (1937) cirrhosis annularis subhymenalis. It has been a matter of dispute why adhesions and fibrosis should more often develop at the junction of the upper and middle thirds of the vagina. It is at this level that the margins of the levator ani cross the vagina, and the contractions of this muscle are said to cause constant irritation. Again, this level is regarded by some embryologists as the developmental border between müllerian ducts and urogenital sinus (Zuckerman 1940). The most acceptable explanation, however, is that at this level the vaginal arteries anastomose with the descending branches of the uterine arteries. These anastomoses, though sufficient to maintain an ample blood-supply during youth and adult life, may fail in old age owing to changes in the vessel walls, which in turn are the result of ovarian underfunction (Novak 1937, Labhardt 1924, 1936). This failure of anastomosis is responsible for trophic changes in the area supplied, such as superficial ulceration and fibrosis.

The adhesions in this case formed quickly. When the patient was seen on Oct. 26, 1948, the cervix uteri was accessible, but on Jan. 14—i.e., eleven weeks later—a relatively firm and extensive adhesion had developed. This must have preceded the hæmorrhage from the endometrium, since the patient had never noted any escape of blood. The $^1/_2$ pint of blood must have taken a few weeks to accumulate, which leaves only a very few weeks for the development of the adhesion. This is hard to explain unless one ascribes the rapid formation and consolidation of the adhesion to the action of the administered œstrogens. There is no mention of this in the literature but I venture to suggest that œstrogens, which are "growth-hormones with a special action on tissues of müllerian origin" (Novak 1947) may accelerate the formation of granulation tissue in the vagina, once opposing areas of its wall have become glued together.

Symptoms

Hypogastric pain and dysuria are consistent with the development of a hæmatocolpos which leads to painful distension of the affected part of the vagina and distortion of the base of the bladder and possibly the urethra. Whether the vomiting was "reflex" or due to toxic action of the œstrogens is a moot point. Dienœstrol is said to be less liable than stilbœstrol to cause nausea and vomiting.

My thanks are due to Mr. C. Heygate Vernon, senior gynæcologist, for permission to publish this case, and to Mr. J. W. Nankivell and Dr. D. Hacking for giving me access to their private clinical notes.

While preparations made for a blood-transfusion and operation, sudden vaginal loss of 1 pint of blood, and the ndition became even graver. Some three hours ision the condition of the limb had remained despite morphine and blood-transfusion.

(Mr. Spalding).—At 8.30 A.M., under general the abdomen was opened through a midline he uterine surface was found to be covered with noses as originally described by Couvelaire (1912). hysterectomy, with the fœtus in situ, was done. ssels were next exposed and explored. The right ac artery was pulsating and of normal size, but l and external iliac arteries were in spasm and The right femoral artery was exposed through a l incision in the inguinal region and found to be y spasm. Right lumbar sympathectomy was next a slow return of pulsation was soon observed. en was closed in layers.

tive Progress.—The patient's general condition ery poor for several hours after the operation, and pressure dropped to 82/60. The beneficial effects od-transfusion, the general treatment for shock, cal treatment (elevation and cooling of the limb) ne apparent, and pulsation returned in the dorsalis y. Next day she seemed much better; her colour and there was strong pulsation in the arteries of the . Convalescence was slow: but she was discharged tory general condition some two months after

p.—Recently the patient was seen again and was in neral health. The right lower limb had recovered , except for a small patch of anæsthesia on the of the right thigh.

DISCUSSION

shock seems obviously to have been responsible evere arterial spasm; operation excluded the r possible cause, embolism. I have not observed ere arterial spasm in patients shocked from age due to placenta prævia or the ordinary um hæmorrhage, but in accidental hæmorrhage k is much more profound. In accidental hæmor- addition to the blood-loss, the possibility of " factor responsible for the local uteroplacental and generalised vascular liability to spasm considered.

ct that only the right iliac vessels were affected planation. I suggest that this may be explained he increased vessel irritability in shock (every is aware that the lightest handling of a vessel e patient is in shock, will send the vessel into and (2) the right uterine obliquity and the erance of the intramyometrial bleeding on the e, which may have led to an increased pressure right iliac artery in this case. Such pressure nds to the surgeon's manipulation.

of interest to note that the spasm affected the ernal and external iliac arteries but not the right iliac. Mr. S. M. Cohen has suggested (personal ication) that this was probably due to the fact e common iliac artery contains relatively little tissue.

e present case a sudden onset of arterial spasm ed a picture identical with that of embolism. Learmonth (1948) has described two cases "in ll the features of embolism are present except bolus." But his cases were cardiac, and the n of shock did not arise.

agonal vasoconstriction may be responsible for nxiety on the part of the obstetrician, who will consider the advisability of an additional major on to save the limb of a patient already gravely accidental hæmorrhage. Since seeing the above have made specific inquiries, and I can report , though less severe symptoms on three occasions. Minor degrees of spasm should subside on conservative treatment. The treatment of the major cases still presents a problem. Sympathectomy will not always relieve such spasms (Cohen 1944), and measures such as high spinal anæsthetic are better avoided in such states of shock. Adequate resuscitation is clearly the key to success, and experience of the traumatic cases indicates that such spasm is likely to yield to it. If a surgeon accustomed to sympathectomy is available, it is a measure that could well be carried out at the same time as any other abdominal operation; it adds little to the operating time or to the shock and is unlikely to do harm. As with embolectomies, there is no need to operate hurriedly on the limb (Learmonth 1948), for delay up to ten hours is permissible.

SUMMARY

A case of acute arterial spasm associated with accidental hæmorrhage in late pregnancy is described.

The right lower limb was completely paretic and anæsthetic, and the patient in agony.

Two factors are held responsible: (1) increased vessel irritability in shock; and (2) obliquity of the uterus and increased hæmorrhage in the right wall of the uterus.

Sympathectomy appeared to relieve the spasm, but it was accompanied by full resuscitative measures, including blood-transfusion.

My thanks are due to Mr. S. M. Cohen for his help in the preparation of this paper; to Mr. R. C. Thomas, with whom I have discussed the case; to Mr. J. Spalding, who operated; and to Mr. J. F. Hackwood, surgeon-superintendent, for permission to publish this report.

Reviews of Books

Rehabilitation of the Tuberculous

(3rd ed.) H. A. PATTISON, M.D., F.A.C.P. London: Baillière, Tindall, and Cox. 1949. Pp. 250. 22*s.* 6*d.*

REHABILITATION has been practised by individual physicians for many years, and its value has long been known to all those who have studied the progressive recovery of patients from sickness to health; but it is only recently that it has been organised into a science with special institutions devoted to its study and practice. It is therefore valuable to have the collected experience of so well known an authority as Dr. H. A. Pattison restated in the third edition of his book.

The work is divided into two parts. The first deals with the concepts of rehabilitation and in the second some of the most important rehabilitation centres, in both Europe and America, are described. The latter section is well illustrated and the author gives interesting comments at the end of most of his brief surveys. The details given of the American rehabilitation centres are clear and concise, but in the accounts of some of the English centres the information needs bringing up to date. It is unfortunate that there is neither mention of the activities of the Remploy Corporation Ltd. nor any account of the Disabled Persons Employment Act of 1944, which has enabled so much progress to be made in rehabilitation in this country.

In the first section, the technique of rehabilitation is described and illustrated by many interesting cases which have passed through the author's hands. There is a particularly valuable chapter on aftercare, which deals mainly with compensation of tuberculosis as an occupational disease. Another very useful chapter is the one on the mental aspects of tuberculosis, and it is noteworthy that the author considers that "the misfits and maladjusted among the tuberculous may be different in kind and degree" but that "it is doubtful if they show more personal maladjustments as a group than are to be found among the general population." It is also reassuring to find that "an adequate programme for rehabilitation is essentially an amplification and extension of the general programme for control of tuberculosis," which means that rehabilitation is part of treatment and should not be considered separately when dealing with tuberculosis.

The book touches very lightly on the clinical side and tends to be rather vague on such matters as selection of individuals for rehabilitation, aptitude tests, and estimation of the patient's fitness after rehabilitation. This is probably because the book is intended for both physicians and laymen. It is rather surprising that allergy and immunity are dismissed in four pages and that there is no reference to the protection by vaccination of children born in tuberculous households. Many long quotations from other writers tend to confuse, owing to the many opinions expressed; this is especially noticeable in the chapter on fatigue. With these exceptions, the book is readable and the subject matter is stimulating and interesting. The author is at his best when describing his own methods at the Potts Memorial Institute, and those interested in the employment of the tuberculous will gain much useful information on the management of a rehabilitation centre. More detail is required on the financial side, particularly as regards the income of those being rehabilitated and the losses that have to be borne by the authorities responsible for the rehabilitation centre. It is estimated that a rehabilitated case of tuberculosis in an industrial employee has cost somebody $4000. The book is clearly indexed and well produced and can justly be described as a "readable record of observations and experience."

Practical Lessons in Psychiatry

J. L. FETTERMAN, M.D. Springfield, Ill.: Charles C. Thomas. Oxford: Blackwell Scientific Publications. 1949. Pp. 342. 30*s.*

Dr. Fetterman's book is a fair example of the uninspired, honest, reasonably well-informed textbook exposition, "sprinkled" (as the dust-cover says) "with excerpts from case-histories," and giving chapter and verse from recent writers. It is built up from lectures delivered by Dr. Fetterman to student officers at the School of Military Neuropsychiatry during 1943 and 1944 and from seminars held in 1945 and 1946. There is a lengthy chapter on treatment of affective disorder by electric convulsions, in which the author seems more at home than in the treatment of psychoneuroses, though in the chapter on the latter theme he is more helpful to the practitioner than many more pretentious therapists.

Public Health in the World Today

JAMES STEVENS SIMMONS, *dean and professor of public health, Harvard School of Public Health.* Cambridge, Mass.: Harvard University Press. London: Oxford University Press. 1949. Pp. 332. 27*s.* 6*d.*

THIS book, with its foreword, is composed of 29 contributions from different authors who presented papers at a series of public-health forums held at the Harvard School of Public Health in 1947–48. The purpose of the conferences was "to develop a clearer picture of the evolution, scope, and objectives of the profession of public health; to focus attention on today's complex problems in the fields of national and international health, and to stimulate realistic thinking about the solution of the problems." It does all those things well but in the main remains an account—a useful account—of public health in America, with little reference to other parts of the world. Martha Eliot (of the Children's Bureau) does something to extend the range of the book by her impressions of the state of children everywhere; Marshall Balfour of the Rockefeller Foundation gives some simple facts about the numbers of doctors, nurses, and hospital beds in India, Ceylon, and China, and about mortality figures in these countries; the medical director of a fruit company tells what his company is doing in South America to promote healthy living in native habitations; the medical director of the Health Service office of international discusses world coöperation in health. American public health ranges over the health as a profession during the 30 years American Public Health Association; medical care in Baltimore; the health and preventive medicine as ments; the development of the U.S. vice as a counterpart of our Ministry of interesting differences); preventive work Army and Naval Medical Services; Veterans Service (which seems to Ministry of Pensions); the views of the American Red Cross on voluntary development of industrial medicine (as poisons) in the U.S.A. The book shows the public health as an entity not to be curative medicine, its expanding scope, and collaborate with other professions and interest of health generally—a useful on the bookshelf.

Hungerkrankheit, Hungerödem, H

Historische, klinische, pathophysiologische, gisch-anatomische Studien und Be ehemaligen Insassen aus Konzentrat HOTTINGER; P. GSELL; E. UEHLINGER; A. LABHART. Basle: Schwabe. 1948. Sw. fr. 28.

IN the spring of 1945 the Swiss made with the Germans to take over the care of soldiers who were severely wounded or sick, ended before this plan could be put into the Allied soldiers were accordingly Swiss authorities, therefore, opened their inmates of concentration camps, and the passed through their hospital service at clinical basis of this book. It opens with a sketch by Salzmann, and the clinical and logical chapters have been written by Gsell respectively. Uehlinger has contributed on the post-mortem findings and morbid Labhart the chapter on tuberculosis. Some —e.g., those on the skin and on the typhoid complications—were written jointly. Thus the subject was handled by an expert, and the produced a valuable if largely descriptive book. it is the same old story, for it is hard to say even about the severest degrees of undernutrit these authors had the great advantage over most predecessors that they were themselves well and surrounded by all the facilities of a well- medical service. They could therefore take an view of the situation and make all the modern tions which seemed to them desirable. Some example, was subjected to plasmaphoretic analy pictures are very revealing, but the general photo is not always first-class, and the lighting and foresho suggest that it was the work of an amateur. The micrography and X-ray reproduction, on the oth are excellent. Many detailed case-histories are and treatment is discussed, but unfortunately no quantitative information about the dietary Furthermore, the book contains little or no exper matter—not even renal-function tests—which that the authors did not make the most of their tunities. The work, though not inspired, may be mended to anyone who requires good modern inf about the effects of overcrowding, neglect, and nutrition—about famine, in other words, and all entails, and has entailed since civilisation began

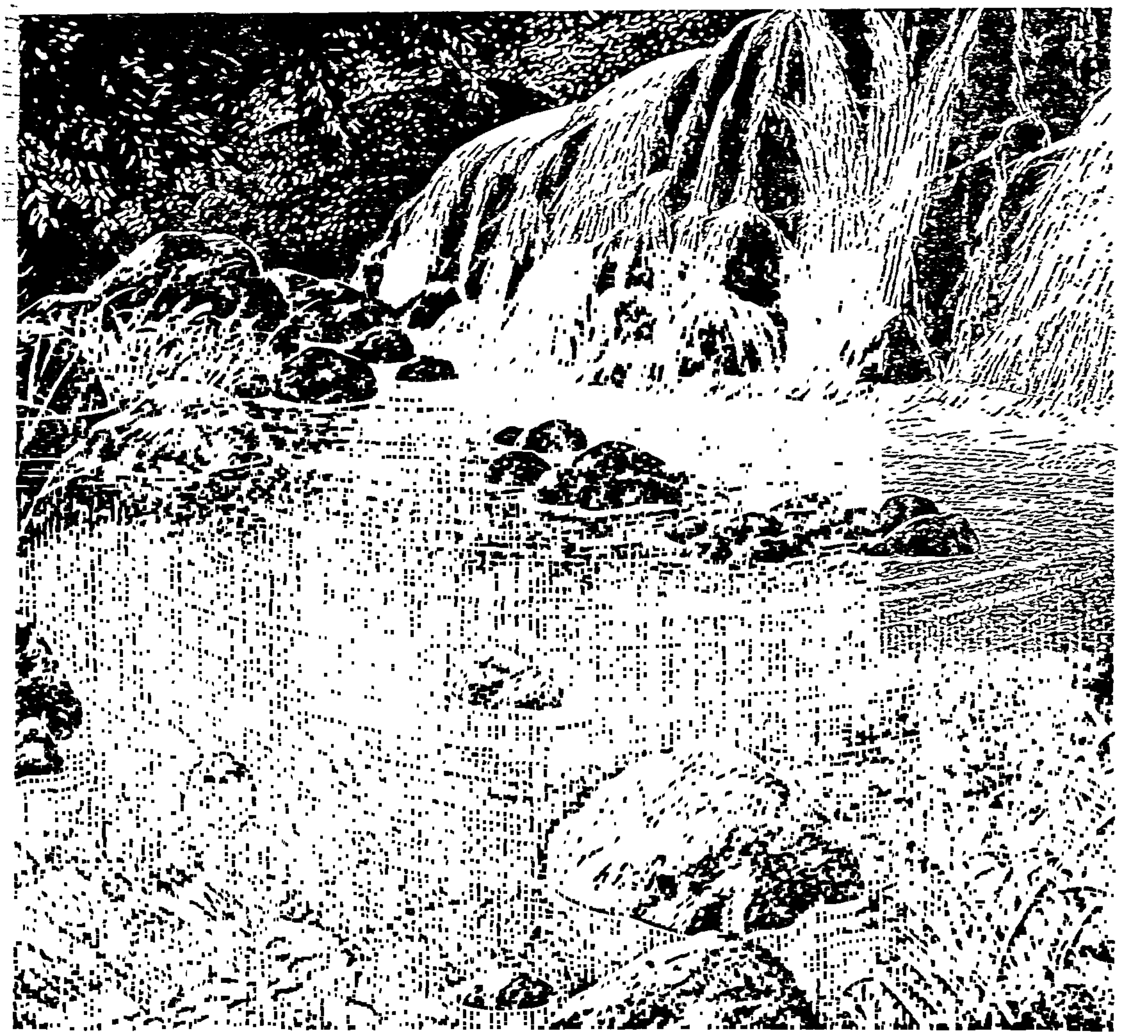
A History of Oto-laryngology (Edinburgh: Livingstone. 1949. Pp. 155. 17*s.* 6*d.*).—This brief by Dr. R. Scott Stevenson and Dr. Douglas Guth much to its larger predecessors, but its authors write ally readably. The chapter headings are so well the material so well sifted, presented, and illustrated feat of compression can scarcely be appreciated ear, nose, and throat specialist will derive pleasure as profit from reading this book.



CRYSTAL CLEAR

the treatment of infections of the urinary tract LBUCID' will not cause crystallisation in the ıal tubules.

lphonamides are still acknowledged to be most ective agents in the treatment of infections of e urinary tract, but for the best results the lphonamide chosen should have three prorties :

) High solubility to prevent crystallisation.

(2) Low toxicity to reduce the chances of undesirable side effects.

(3) High bacteriostatic activity in the urine, i.e. it should be excreted as active sulphonamide.

'ALBUCID' (sulphacetamide) fulfils all these criteria. It combines high solubility with low toxicity and is excreted by the kidney in bacteriostatically active form.

PRESENTED AS

LBUCID' ORAL TABLETS

in tubes of 20 and bottles of 100 and
500 tablets. Each tablet contains
0.5 Gm. (grs. 7½) Sulphacetamide B.P.

prescription for **WINTER PROTECTION**

In the vitamin alphabet, 'A' and 'D' are the recognised initials of protection. Winter's arrival underlines the importance of these vitamins — and of the Adexolin preparations which present A and D at high concentration. Adexolin Capsules are meant primarily for adults. The normal routine is one or two capsules daily throughout the cold months, with a larger dose if infection threatens—for instance, when the onset of a cold is suspected. For infants and children, Adexolin Liquid provides an equally sound and economical routine, fortifying the body's resistance to infection through the *natural* mechanisms.

the clinical assistant: he may have a very
time because he is often given the less
sting" cases—those with vague and indefinite
ms. Actually, to exclude possible disease in a
with a minor complaint is ten times harder
liagnosing a straightforward case of major
so in practice the junior man is being given
ost difficult work. If the more senior men
larger share of these cases they might save
admissions and investigations which the junior
tes through over-caution or inexperience.
r, the clinical assistant (as in the example
ed by Dr. LIPSCOMB) does not do inpatient
and once he admits a case he loses contact
t. There is much against this system, and
mes it would be better for outpatient clinical
nts to be converted into housemen and work in
rds. Another cause of loss of continuity is the
e of admitting a case "to come into medical
" with no guarantee that it will be a ward belonging to the firm who saw the outpatient. Whenever possible a firm should admit its own outpatients. Many of us, wandering in some far-flung ward, have accidentally come across an ex-outpatient of our own; and, as we mutter "I didn't know you'd come in yet," and watch the patient's features light up at the sight of a familiar face, we feel guilty that we have lost touch with him.

The houseman's lot is not a happy one either. Often he has to decide what investigations are to be done; and, in order to ensure that his chief shall not call in vain for any test, he often orders too lavishly. If he has to decide which cases are to be followed in outpatients he may be too careful and refer too many. The houseman ordering investigations must learn to catechise himself, saying, "What might I find and what would I do if I found it?" He must join with his registrar in seeing that his patient's perambulations are not unduly extended. The attitude "Let's send her back to outpatients" or "let's order this or that test because there *might* be something organic" defeats its own ends, for the departments get cluttered up with vague cases so that there is not time to go into them properly. Outpatient departments are not meant to provide cover for the doctor but to provide comfort for the patient; it is better to go deeply into a few likely cases than to hurry superficially over a large number of possibles.

As Dr. LIPSCOMB points out, much responsibility devolves on the first assistant (now called senior registrar). He can make it his duty to see that every patient receives an informative and helpful talk before his discharge (unless his chief has already given this). He can see to it that letters are written promptly and contain not only a list of investigations but also helpful interpretation and comment upon them. (The practitioner wants to know the best dose of digitalis for Mrs. A; he is less concerned about her circulation-time.) And he particularly can help to achieve that essential coördination that will give patients a feeling of continuity.

Lastly the chief. He can do much to ensure continuity of doctor and policy by coördinating and supervising the activities of those working for him. Not only will the wheels then turn more smoothly but they will turn faster (for the increase of speed when a doctor sees a patient he already knows is remarkable). He can strive to arrange his assistants' work and holidays in such a way as to prevent the "bird-of-passage syndrome" described in Dr. LIPSCOMB's article, and he can, by conferences with his juniors, curb enthusiastic over-investigation and unnecessary reference of cases to other departments. Above all, he can see that on his rounds he not only holds important discussions with his retinue but spares a few words of encouragement and explanation for the patient. Of course he may be so burdened with other medical commitments that he largely stands aside from intervening in his patients' affairs, leaving decisions to the postgraduate assistants whom he trusts so well. He knows his patients will be well cared for; yet, as Dr. LIPSCOMB says, this standing aside "may make a subtle contribution to the failure of medical coördination." Perhaps chiefs should exchange some of their committee work for clinical work and try to achieve a larger number of visits. Could not the registrar class take a share of some of the committee work? They might be more impatient and intolerant of the cumbrous procedures—the shelving of decisions and the shuffling of responsibilities between committees, subcommittees, and boards, but by their very impatience they might imbue committees with more vigour and effectiveness. Another point: is it wise to label the patient as being under Dr. X except when Dr. X sees him regularly? Might not registrars have their names displayed on their desks, so that patients know them by their own name, and should not senior registrars have appointment cards of their own?

Many of these alterations may be impracticable in an established system: but there are other possible approaches. One good way of narrowing the gap between practitioner and hospital is to invite local doctors to hospital clinical meetings (designed specially for them) and to arrange sherry parties where they can exchange ideas with the hospital staff. Both these practices have worked well at some of the non-teaching hospitals. The keen practitioner, too, who comes to visit his patient in hospital should be spared a few moments' talk by registrar or houseman and not be made to feel that he is poaching. Another innovation now started at several hospitals is the printing of small pamphlets which are given to patients on entry. These little brochures explain in simple words some of the things the patient wants to know and tell him a little about the hospital. A wisely worded pamphlet can inform and interest the patient and explain everything from visiting-hours and ward routine to the way to get letters posted, or the correct way to deal with false teeth (please ask sister for a bowl and do not put them in *your locker wrapped up in a handkerchief*). Where they have been tried, these pamphlets are a great success and have certainly helped in seeing the patient through.

To summarise, the problem of "seeing the patient through" exists, and will continue to exist, for the same reason that a departmental store, though it gives a fuller service than a local shop, can never achieve the same personal touch. Dr. LIPSCOMB has done a service in bringing this problem to notice in so vivid and stimulating a way, and it is to be hoped that everyone concerned will seek methods of solving it.

Staphylococcal Cross-infection

THE staphylococcus, like the poor, is always with us, and we have come to accept its various manifestations —from infected cuts to boils and carbuncles—as necessary if unpleasant evils. When, however, pemphigus spreads through the maternity nursery, or a series of infected wounds crops up in a surgical ward, the hospital authorities are rightly alarmed and usually end by invoking the bacteriologist.

The successful application of the work of GRIFFITH and LANCEFIELD in tracing the sources and modes of spread of streptococcal infection raised hopes of similar successes with the staphylococcus, but early attempts to classify the organism were disappointing. The first advance was the recognition that all potentially pathogenic staphylococci, whether or not they produced golden-brown pigment, were ca coagulating human plasma: but in the s the source of outbreaks it was found that 40 contacts carried coagulase-positive staphyl the nose and upwards of 20% on the hand therefore necessary to subdivide pathogenic s cocci as GRIFFITH had done with Lancefield streptococci. This has been attempted—and part accomplished—by both serological typing.[1] These techniques, which require m and experience, are still being used in onl laboratories; but already they are yielding r great significance. It has been established t *carriers of staphylococci are usually persist* carriers of the same type,[2] and that the probably contaminated from the primary colonisation in the squamous epithelium of th vestibule,[3] *although the occasional heavy skin and the profuse growth of staphylococci* f scars, suggest that the hands may sometimes focus and not merely the vehicle for the organism. With superficial staphylococcal like sycosis barbæ, boils, and infected staphylococcus is often derived from the nos of the patient himself, and sterilisation of th vestibule or the skin surrounding a wound to prevent the occurrence or recurrence of infections.[4]

What happens in hospital infections? autogenous, or is the staphylococcus derived an outside source as with most streptococcal tions? The topical interest in the increasin of *penicillin-resistant staphylococci* in hospit munities and the use of phage-typing are gi part of the answer. Different workers[5] hav that 40–60% of staphylococci from hospital *are resistant to one or more* units of penicil that a similar high rate of resistant strains in nasal carriers among the hospital staff, wh incidence of resistant staphylococci in the community is still around 5–10%. In the cases cultures were sometimes obtained fr lesion after penicillin had been used; so the re strain may have been present in small number *the onset. However, in this issue* Miss R and Dr. THOMSON report from Sydney that hospital cases infected with penicillin-resistant lococci, the organism was derived from an *source in at least 54, and that only* 8 patients (a total of 196) had primary infections with pen resistant strains. Both the Australian workers BARBER and WHITEHEAD[6] have found that penicillin-resistant hospital strains belong to phage types, while the sensitive staphylococ distributed among many different types—a which substantiates the view that staphylo infections in hospital are mostly cross-infection the prevalent types.

The next step was to trace the mode of spre a pointer is the close correspondence, fou

E and Thomson, between the phage types ses of the staff and in the lesions of the cross- patients. But it must not be too hastily i that nurses are the main foci or even the f infection. The high nasal-carrier rate of mic strains among them may simply reflect lococcus-contaminated environment in which t and bed-linen may be important reservoirs air a means of dissemination. It seems likely gh this was not apparently investigated— air number of the patients were also nasal of the prevalent types and may themselves ected their various lesions. It would also be assume that a staphylococcal nasal carrier as dangerous to his neighbours as is the occal nasal carrier. The infected wound and are possible alternative sources, and further ation is needed before a particular source or f spread is incriminated. The data so far that staphylococcal cross-infection may be in hospital and call for better standards in and nursing practice—for example, by the "no-touch" dressing techniques and dust- sive measures—instead of a too easy reliance biotics. Casualty departments, surgical and ty units, and the ear, nose, and throat wards e most vitally concerned, and we would urge he need for "cross-infection" committees to earer that first requirement in any hospital— shall do its patients no harm.

Graphite Pneumoconiosis

HITE, or plumbago, which is a crystalline carbon, is perhaps best known as the "lead" ils or as the "black lead" used for polishing and grates. It is also used in making plumbago es, pigments, and lubricants, as well as being a uent of crucible steels and alloys and some of rubber. Commercial or natural graphite, is mined in the U.S.S.R., Korea, Madagascar, , and elsewhere, contains usually about 10% silica, but some samples have as much as An artificial form of graphite made from onsists almost entirely of carbon and is used bon electrodes. For most purposes graphite be ground to a fine powder, and some methods iding are very dusty. Until recently the dust phite has not been thought to damage the or at most to set up a mild form of pneumo- is. And indeed, the evidence that lung damage ise from artificial or nearly pure graphite, as ed to natural graphite which contains free silica, slender.

e light has been thrown on the subject by ecent papers describing the histology of the of workers inhaling natural graphite dust. NE and his colleagues[1] describe the clinical, graphic, and occupational features in two men ad inhaled dust containing graphite, free silica, ertain silicates. Both men had massive pro- ve fibrosis of the lungs superimposed on dust lation. At necropsy the lungs were black from ite dust, and this dust had also mixed with bron- mucus to form a slimy glistening black secretion oozed from the cut bronchi. Massive nodules of silicosis were present, some of the masses having broken down to form ragged cavities containing a similar black secretion. The histological pattern of the lung lesion was that of a dust reticulation with superimposed conglomerate nodules of silicosis and mixed nodules resembling those found in the lungs of coalminers. "Graphite bodies" similar to the "anthracosis bodies" of coalminers' lungs were present in large numbers. The three men whose cases are fully described by Harding and Oliver[2] had more clear-cut occupational histories, in that they were exposed to the dust created by grinding natural graphite without the addition of free silica and silicates. These writers also describe the radiographic appearances in other workers employed at the factory, where two of their fatal cases had worked; and to complete the picture the results of animal experiments are included. The clinical and radiographic features of one of their cases were previously described by Dunner,[3] who focused attention on the subject but was misled by the workers' statement that they had been handling "pure" graphite. The gross morbid anatomy and the histology of the lungs of the three fatal cases are similar to those in the two cases described by Gloyne and others, both teams of investigators drawing attention to the striking resemblance between the pneumoconiosis of graphite workers and of coalminers.

Harding and Oliver say that long exposure to substantial concentrations of graphite dust can produce a pneumoconiosis which may result in complete incapacity for work and may ultimately be fatal. A striking feature of many cases is the relatively slight physical incapacity in relation to the radiographic findings, and it appears that graphite pneumoconiosis is often well tolerated until the late stages. The radiographic picture is not that of classical silicosis, nor is the histology typical of silicosis: nodules resembling those of classical silicosis may be found, but more commonly the picture is one of pigment aggregates with linear or radial fibrosis and an accompanying focal emphysema. In advanced cases massive areas of fibrosis occur without definite nodular fibrosis.

It was Thackrah of Leeds who said, in the early part of last century, that all dusts may damage the lungs but that some may damage them more than others. The more the effects of various dusts on the lungs are investigated the clearer it becomes that when even small quantities of free silica are present in mixed dusts serious lung fibrosis may be set up. Until lately it was thought that free silica must be present in large quantities (of the order of 60–80%) to cause silicosis. The mixed dusts containing small proportions of free silica do not always cause classical silicosis with its typical whorled nodule; the pattern of the fibrosis is often more linear and radial. This was pointed out by Harding and others[4] in their descriptions of the lungs of boiler-scalers exposed to the inhalation of dust containing carbon, iron, and silica, the free silica comprising less than 6%. Graphite pneumoconiosis (from exposure to the dust of natural graphite) evidently falls into the same category.

Annotations

CRYSTALLINE TOXIC FACTOR FROM AGENISED FLOUR

Sir Edward Mellanby's[1] alarming discovery that flour prepared with nitrogen trichloride ('Agene') can cause "canine hysteria" has been followed by an intensive investigation of its possible adverse effect on man. This study has so far brought to light no substantial evidence that it harms man; but workers have been hampered by their ignorance of the responsible factor.

Moran[2] soon found that this factor was associated with the protein fraction of flour, since when the search has been steadily narrowed. Now Moran and his colleagues[3] at the Cereals Research Station appear to have isolated the factor itself. This is a crystalline material, giving a constant atypical ninhydrin reaction. Twice recrystallised from aqueous ethanol, the material retains the same degree of toxicity. The needle-like crystals melt sharply with decomposition at 232°C. A preliminary qualitative test has revealed an appreciable sulphur content. Identical crystals have been prepared from separate batches of agenised flour, but have been absent from unagenised flour treated as for the isolation of the crystals. The substance is highly toxic to rabbits, in which it produces convulsive fits; it is also markedly toxic to the organism *Leuconostoc mesenteroides P*-60 at a concentration as low as 5 µg. per ml. of liquid medium.[4]

A HUNDRED CENTRES?

At the Trades Union Congress at Bridlington last week, the representative of the Association of Building Technicians proposed a resolution calling on the Government to sanction the building forthwith of a hundred health centres, and to plan for the completion within ten years of a full programme of health centres for the whole country. The resolution was supported by the Medical Practitioners Union but opposed, we are told, by the platform—not apparently because the leaders of the T.U.C. were out of sympathy with the demand for health centres but because they doubted the wisdom of tying trade-union policy to so specific a number of centres as was suggested. Nevertheless the resolution was passed by an overwhelming majority.

From the moment they received the Minister of Health's circular of January, 1948, many local authorities banished health centres into the Never-Never Land of long-term planning; and we can only welcome any effort that brings them back into the realms of reality. In the debate at Bridlington it was argued that the immediate building of a hundred centres could be undertaken with no more than a 1% reduction in the rest of the present programme of building and civil engineering. It is, of course, for the Government to say whether the country can yet afford the capital expenditure and the diversion of constructional effort that even this 1% load would involve; but there is certainly a very strong case for starting this new development on an appreciable scale at once. The profession would be right in opposing the indiscriminate building of health centres before there has been proper experiment in different types of practice in different types of centre; it would probably say that ten years for the full programme is far too short a time in which to apply fully the experience that will be gained in the first centres—experience that may considerably modify present conceptions of health-centre design. Again a hundred centres may be more than we essentially need for these first practical tests; they may, indeed, be we should find it possible to launch at once wi unanimity of purpose of doctors, executive and local health authority that will be in if initial difficulties are to be overcome. knowledge that the continued popular demand faith in health centres has been so strongly e in this Congress of Trades Unions will certainl all who have continued to pursue the vision lately, the receding vision—of general practi modern conditions.

THE PHAGE-INFECTED BACILLUS

The parlour tricks of the eighteenth-century now seem as ingenuous as ingenious, yet philosophical trifling the modern methods of all have developed. So it is that mere improv optical technique applied to minute bodies—dar illumination with the bright sun of Pretoria, and phase-contrast microscopy—are per se no idle amusements to the bacteriologist until applied to his particular problems. These have in fact more than justified themselves, and there could be no better example than Boyd's the phase-contrast technique to observe the mo of *Salmonella typhi-murium* when brought into with specific bacteriophages. In general the "in of the bacillus was revealed by the developme enlarging pale area in its substance. A fatal out signalled by the distension and bursting of the the attainment of symbiosis by the appearance areas whose enlargement was limited and by d of the shape of the bacillus; a lysogenic sym similar phenomena which are easier to apprec the illustrations than to describe.

The camera cannot lie; but, rememberi cunning photographs which look like sunrise in desert and are in truth the bristles of a tooth close range, we have learnt to be cautious in conclusions from a technique of which few of experience. However, if the pale areas whic describes are not the multiplying phage itself, Lombard Street to a china orange that they are in connected with the infection, since they are absent from organisms which have had no cont a specific bacteriophage. This is a new tool bacteriologist, and we shall look forward to future use and possibly abuse. Perhaps parallel nations with the electron microscope would not only further information but also a usefu on the validity of the interpretations of techniques.

ASPIRIN AND THE ACID-BASE BALAN

Conflicting accounts[2,3] of the effect of sa on the acid-base equilibrium of the blood in child Farber and others[4] to undertake a comprehensive in ten healthy men. The subjects were kept during the experiment and were given 1·3 g. of by mouth every hour for 8 doses and then 1·6 g. 9th hour, making a total of 12 g., which is the higher dosages recommended in the treat rheumatic fever. Eight of them developed sym of salicylism after the last dose. In seven ca symptoms persisted for about 8 hours, and the man still complained of tinnitus after 48 hours. salicylate, serum pH, total CO_2 content of the respiratory volume, respiratory rate, and red-ce were estimated before medication was begun an

TREATMENT OF THE TRAMP

PS the most interesting section of the latest
om the National Assistance Board [6] is the one
ures taken to deal with people who were formerly
as "casuals" or vagrants. With a new sense
cy, the label has been changed to "persons
a settled way of living," but the essential
remains. Fortunately its dimensions, if not its
have greatly changed from what they were in
s of industrial depression. On a night in May,
fewer than 16,911 men "on the road" were
elter in what would now be called a "reception
By September, 1939, the comparable figure
7, and the war reduced it further. After the
upward trend began; but even by last December
l number of men, women, and children accom-
l in these centres was only 2368.

e past, the main emphasis of treatment lay on
elter, medical care, and disinfestation. (As a
mallpox outbreak showed, the infected migrant
se rapid dissemination.) With the new outlook
lic assistance in general, the focus of interest
shifted to re-establishment, whereby persons
at a settled way of living may be influenced to
more settled life." The methods adopted
ly vary as much as the individuals themselves
early useless to try to assuage the wanderlust of
er men of the "tramp" type, but much can be
r youths who have run away from home after a
or some indiscretion. Medical care still plays a
ut social reablement remains the prime thera-
agent. Within the centre itself firm discipline is
l; younger men, for whom more hope can be
it, must be divorced from the influence of the
ed drunkard or gambler whose bravado in defiance
ority is only matched by his boasting of the ease
hich he can live at public expense. For the
of the National Assistance Board and their colleagues in the Ministry of Labour the attempt to place and maintain men in employment can be a dispiriting task. In one centre, of 17 men who accepted employment in the course of a week only 2 were still working at the end of it: but some young men have volunteered to train in coalmining and gone on to work successfully in the mines. As long as it is possible to salvage even a few men from a life of degradation, the board's officials are determined to believe that where there's life there's hope and to encourage as many as possible to live as normal decent members of the community.

The modern wanderer no longer goes on foot; by lorry-jumping he can travel hundreds of miles in a day. New centres are therefore being set up only at considerable distances from each other. It is clear that physical care and occupational readjustment at such centres offers no real solution to this problem. In social work, as in medicine, prevention is better than cure, and the hope for the future seems to lie in the provision, by either municipal or voluntary effort, of good cheap hostels for young working men.

PHARMACY AND PHARMACOLOGY

THE pharmacist is no longer true to Romeo's description:

> "Sharp misery had worn him to the bones:
> . . . and about his shelves
> A beggarly account of empty boxes, . . ."

On the contrary, so prosperous and prolific is the pharmaceutical industry today that we may more appropriately exclaim with Nerissa: "They are as sick that surfeit with too much as they that starve with nothing." The reason for this happy transformation may be found in the chairman's remarks to the Pharmaceutical Conference at Blackpool this week. In his address Mr. Norman Evers maintained that pharmacy is not a science in itself but an art that makes use of many sciences; and in developing this theme he referred to the various divisions of his subject, most of which are so technical that any physician hearing him must have acknowledged the mercy of providence which placed him at the bedside rather than in the laboratory.

In most professions there is a tendency to define the curriculum precisely, to be wary of expansion, and to resist encroachment from without. The pharmacist takes the opposite view, expressed long ago by Daniel Hanbury: "All science is interesting to us since almost every scientific discovery may sooner or later, directly or indirectly, yield some results profitable to pharmacy." Paradoxically this liberal philosophy has led to intensive specialisation, but the profession and trade are to be complimented on the coördination between their various branches; the leading pharmaceutical manufacturers have shown what can be achieved by imaginative organisation and unrelenting effort. Still, the pharmaceutical industry has its problems. Mr. Evers referred to one of them—namely, patents, which he described as "the bugbear of the industrial worker." A by-product of the patent system is the multiplication of preparations of the same chemical substance, resulting in confusion and exasperation among not only doctors but pharmacists themselves. The solution lies in compromise between the legitimate claims of original workers on the one hand and the best interests of the community on the other, and this is not easy to attain. Pharmacy has considerable achievements to its credit, but here, as in other walks of life, most men with inventive talent still sell their services to the highest bidder; and interference with this relationship may deprive the public of great advances in the means of treating and preventing disease. Belief in private enterprise is nowhere stronger than

t of the National Assistance Board for the year ended
31, 1948. H.M. Stationery Office. 1s. 3*d*.

among manufacturers of pharmaceuticals, but the most enlightened firms are aware that patents may be open to abuse by the creation of monopolies; and critics of large-scale amalgamation of industrial concerns are quick to point out that this process is fraught with special dangers, including the virtual extinction of private enterprise and fair competition.

Mr. Evers very properly made a plea for the proper organisation of pharmaceutical research, indicating in particular the need for more research on behalf of the *British Pharmacopœia* and the *British Pharmaceutical Codex.* "It is surely important from the public point of view," he said, "that the official pharmaceutical formulæ should be the best possible and that the amount and quality of research which is applied to their formulation should be at least equal to that which would be given to the subject by a manufacturer." Nobody will dispute this, but many doctors are not aware of the scope of the *B.P.* and the already high standard of official preparations. Perhaps this ignorance is due to the fact that most medical students are taught pharmacology by lecturers who are not clinicians, and therapeutics by clinicians who are not [illegible] further official publication—the [illegible] must become increasingly valuable to the practitioner as a reliable source of prescriptions incorporating official remedies; and it would be well if the student could be introduced to this book at the start of his clinical training.

PREDISPOSITION TO DIABETES

HEREDITY is now generally accepted as an important factor in the ætiology of diabetes mellitus, but neither the mode of transmission nor its precise rôle is clear. A report from Glasgow,[1] based on a group of 1309 diabetics, provides some new data. In 997 of these cases (91·4%) the age at onset of the disease, as judged by symptoms, was over 40 years. There were 2¼ women to each man in the whole series, though up to the age of 40 the sexes were about equal. After 40 the frequency in women rose rapidly, whereas in men the rise with increasing age did not become obvious until 50 and even then was much more gradual than in women. This high frequency in middle-aged women was confined to married women, and seemed to be related to previous childbearing. In women maximum weight was significantly greater in diabetics than in controls from the age of 20, but male diabetics were no heavier than normals until after 40. Married women were heavier than single women in both diabetic and control groups. Mean systolic blood-pressures were not significantly higher in male diabetics than in controls; in females, however, the pressures were significantly higher in diabetics than in controls after the age of 30, and this could not be correlated with either obesity or previous childbearing. The onset of symptoms was associated with sepsis in 6% of cases; but these were mainly middle-aged patients, and the proportion (18%) with a family history of diabetes did not differ greatly from the proportion (23·3%) among all others in the series. Such a family history was obtained less often as the age of onset increased; but family history was unrelated to the severity of the disease. A family history of diabetes was as common among diabetics with obesity, hypertension, and sepsis as among those without these complications; while the proportion of familial cases was significantly lower among female diabetics with large families. Thus there is no proof of partial sex-linkage and no convincing evidence that the age at onset is determined by heredity. The recognised ætiological forces can be divided into: (1) hereditary, and (2) others—including obesity, childbearing, and sepsis —which increase innate susceptibility.

The hereditary factor is discussed more fully by Harris,[2] who has studied over 2000 patients a College Hospital. He finds that the juvenile a adult form of the disease is much more likely to among the sibs of juvenile and young adult than among the sibs of middle-aged or elderly d —suggesting that the disease that starts in y young adult life is genetically distinct from that in later life. This is supported by the ob that when diabetes developed before 30 there was but significant increase of cousin marriages in the —an increase that was not evident in respect of developing after 30. On the other hand, not monly one or other of a young diabetic's parent diabetic, usually with diabetes of late onset; scarcely in keeping with the hypothesis of two distinct conditions. The discrepancy could be e however, on the hypothesis that the milder case onset are heterozygotes (i.e., carriers) for the s gene, whereas the more severe juvenile or adult cases are homozygotes. A further com is that among the siblings of female diabetics is commoner in men than women, whereas am siblings of male diabetics the disease affects sexes more equally. Yet another confusing f that the later the disease starts, the less likely reduce effective fertility. But if this were t factor determining the frequency of the effective the population, the disease would be getting less of more common. This apparent discrepancy be explained by assuming that some non-diabetic carry one or more of the genes which in ap combinations give rise to the juvenile form of the in offspring.

HYALURONIDASE IN PÆDIATRICS

HYALURONIDASE, a mucolytic enzyme obta many sources, including mammalian testes and has been found to promote the absorption injected intramuscularly or subcutaneously[3]; accelerates the absorption of penicillin, strep adrenaline, and procaine. The benefit of th enzyme is perhaps most evident in the treat children, where intravenous therapy is often frau difficulty; and in this issue Professor Gaisfor Dr. Evans show that dehydration in children as well to saline administered subcutaneou hyaluronidase as to intravenous infusions, altho response is rather less rapid.

Schwartzman[4] reports that of 158 children only allergic to hyaluronidase in the purest form av In his experience the optimal dose for parenteral in 80 µg. per area per dose, and any increase this amount does not further hasten absorption Gaisford and Evans, he finds that plasma is a when given subcutaneously with the enzyme; an infant with serious diarrhœa and an initial protein level of 4·7 g. per 100 ml., absorption took only after the protein level had been raised by a nary intravenous infusion. In anæmic childr received subcutaneous injections of whole bloo hyaluronidase, absorption was confirmed by hæmoglobin estimations.

If the potential value of hyaluronidase i exploited, a standard and highly purified pre will be needed. The material can be easily prepa bovine serum, which may be had in fairly large qu The potency of the enzyme is easily tested.

DR. N. HAMILTON FAIRLEY, F.R.S., Sir HARTLEY, F.R.S., and Prof. J. MCMICHAEL, F.R.C. been appointed members of the Medical Research from Oct. 1.

purpose of this investigation was to discover the of continued unemployment among registered d men when a state of nearly full employment .; to note to what extent joint medical and lay ls could secure permanent resettlement; and nment on the medical aspect of the problem.

he end of a year the employment position of the s of this group was reviewed to check the accuracy of the initial prognosis and to ascertain the success of the joint interviewing and its placing results.

MEDICAL FACTORS

Of the group of 50 men examined, 8 were aged 18–30, 11 were aged 31–40, 23 were aged 41–55, and 8 were aged 56–64. For a reliable prognosis total employment record had to be considered, since more often than not, together with medical and social history, it revealed a trend or changing attitude towards employment. All 50 men were substantially disabled and eligible for protection within the meaning of the Act. Apart from one man who sustained his disability within the preceding six months, the remaining other disabilities were long-standing, and many were congenital and many from the 1914–18 and 1939–45 wars. Much of the medical information available was out of date and had been provided by military hospitals in circumstances entirely different from those existing at the time of interview. Medical opinion appeared to have been given in many cases without consideration of the social history and, more particularly, the occupational record. A feeble-minded delinquent aged 22, who had been sent to seventeen jobs within the past year and had worked at five of them for a total of three months, was reported as being suitable for training in agriculture. His application for training was subsequently rejected.

The principle of medical examination with a view to assessment of functional capacity and selective employment without careful scrutiny of past work record and without the active coöperation of the resettlement officer was unsatisfactory. The most important single medical factor was a mental one, in the main that of personal attitude towards disability. This disability-consciousness was associated with a tendency to reel out symptoms and disabilities with extravagant ease, and the effect of their apparently imposed limitations on the man (" I can't do this, I can't do that " attitude) was sufficient to deter any prospective employer. Disablement resettlement officers (D.R.O.) were handicapped as placing officers in having to accept statements of disability from the men, and they seemed powerless to deal with many of the men because of their regard and literal acceptance of medical opinion on the limitations imposed by disability as shown on form D.P.1. More confusion arose in the following type of case: a man complained that he had a crushed foot, chronic bronchitis, stomach trouble, and rheumatism; he had been continuously on National Health Insurance sickness benefit from 1932 to 1937, yet, according to the medical report, he was not disabled.

Though not justified in attempting accurate diagnosis of mental disability, we agree with Lewis et al.[1] that one can record its existence without forming an exact diagnosis. In many cases psychiatric evidence from service medical records was available. The work record is a very important test of stability. It also provided valuable evidence of the relations between the man and his employers and fellow-workers, and, together with his educational record, behaviour record, domestic relations, and the result of interviews with the D.R.O., assisted in the assessment of his personality and emotional attitude. According to the records available to the D.R.O., 4 men were suffering from psychological and 46 from physical disability; but in fact it was found that 7 were physically disabled, 17 mentally disabled, and 26 disabled owing to a combination of mental and physical factors. There was a tendency for the disability label to be altered and for mental disability to assume an organic title, as noted by Halliday.[2] Thus, a man with a severe anxiety state, with tremors, and a recent history of long treatment in a mental hospital, was being dealt with as a case of chronic fibrositis.

[1] Lewis, A., Capel, E. H., Bunbury, D. E., Fraser, R. *Brit. J. industr. Med.* 1945, 2, 41.

[2] Halliday, J. L. *Brit. med. J.* 1935, i, suppl. 85, 99.

The striking feature of the group was the pathological attitude of resentment, aggression, depression, and, in many, severe anxiety. Apart from the fact that they were mainly severely disabled, no comment seems necessary on the 7 with purely physical disability. The 17 cases of primarily mental disability included antisocial or psychopathic behaviour (6 cases); feeble-mindedness (5 cases); psychoneurosis (5 cases); and schizophrenia (1 case). Of these, 4 had minor physical disabilities, 2 slight bronchitis, 1 club-foot, and 1 with arteriosclerosis and premature senile changes. The remaining 26 cases included a wide variety of physical disability complicated by psychoneurosis, antisocial tendencies, or feeble-mindedness: 2 of these men urgently needed institutional treatment.

Most of the men were regularly or intermittently attending a general practitioner for treatment. The Labour Exchange records revealed that, during the preceding three years, 28 men had had spells of sickness, lasting 1–99 weeks, average 22 weeks. This recorded sick absence comprised domiciliary, hospital, sanatorium, and mental-hospital treatment. There was no record of sick absence during spells of employment, but many of the men said that sickness had seriously interfered with the jobs they had done in the past, either causing bad time-keeping or leading to their ultimate discharge or voluntary relinquishment of the job.

WORK RECORD

Attitude to work seemed paradoxically related to the extent of disability. Of the 16 classed as very severely disabled, 12 were well disposed towards work, and only 4 could be described as having a bad or indifferent attitude. Some of the more severely disabled had a will to work which was beyond their remaining abilities. The disquieting feature was that, of 34 men with slight or moderate disability, only 11 showed an attitude towards employment which was likely to commend them to employers, whereas 23 showed indifferent or frankly poor attitudes. Many of the older men, in spite of age plus disability, had fair attitudes towards employment.

At the time of interview the duration of unemployment for each man ranged from $1^{1}/_{2}$ to 33 months, the mean being 10 months, as follows:

Duration	*No. of cases*	*Duration*	*No. of cases*
6 weeks or less ..	6	13–18 mos.	8
7–13 weeks ..	8	19–24 ,, ...	2
13–26 ,, ..	12	25 mos. or more ..	8
27 weeks–12 mos. ..	6		

This does not imply that the men had worked for any length of time before becoming unemployed. Employment record varied between good, where the man had spent his whole life in perhaps one or two jobs, only, and bad, where there had been very long spells (up to ten years in some cases) of unemployment, or where a man, though not unemployed for long periods, had been engaged in a great variety of jobs, each of short duration, interspersed with periods of unemployment. One man, for example, had been sent to 99 jobs in the past two years but had held only 50 of them.

Of the 50 men, 38 had been in the Services, 19 of them in the 1914–18 war and 19 in the 1939–45 war. In 15 cases employment, or unemployment record, had not been altered by the period of military service. It was possible to detect slight interruption in 3 cases, and in 13 cases the effect had clearly been unfavourable to the man's subsequent record. Service had completely unsettled 7 of the men, and they had done little or no work in consequence.

Of the 50 men, 2 were capable of skilled work and 7 of semi-skilled work; the remaining 41 were unskilled—
i.e., fit for labouring. In the semi-skilled
were continually falling back on completely
work and could really be classed as general

EXTENT AND EFFECTS OF SUBSIDY

From various sources 13 men were receiving
sum of 20–30s., 11 received 31–50s., 8 received
12 received 71–90s., 4 received 91–110s., and 2
more than 111s.

Most of the men drew unemployment
extended benefit after they had exhausted their
benefit, 5 received money from public-assistance
ties, and 20 received war pensions (12 from the
war, and 8 from the 1939–45 war). A few
family allowances, and some received money
children who were working or from married
living at home. Four had received workmen's
pensation for industrial injuries for periods of
weeks, fifteen months, two years, and three
man had unsuccessfully claimed workmen's com
7 of the wives of the married men were wor
men had between them 22 children working,
home, and contributing to the household; and
married children living with their families
household and making contributions.

The older married men and widowers appeared
resigned to unemployment. This may have
to their better financial position or to their larger
ence of unemployment. Many were quite ha
live on the bare subsistence level provided by un
ment benefit. A few undertook a little casual wor
ing lorries, helping in the market, running me
earning a few shillings a day when they felt like
of those with the larger subsidies, in spite of th
of skill, inferior physique, and infinitesimal va
the labour market, were refusing proffered jo
wages less than £5–6 per week (more than the
receiving from the various forms of allowance
amounted to a refusal to work. Many of the
wives and older children working had exchan
household rôle of breadwinner for that of ma
work and were content to perform menial d
duties and mind the younger children.

st pitiful cases were the young single men and who were separated or divorced from their en mentally defective or unstable, and who quently run into a sea of troubles, the orderly police custody, and had gradually descended scale, left home for lodgings, for a single rented which they prepared their own food, and, r a hostel. This deterioration was apparent in their living habits but also in their neglect al appearance, particularly clothes and shoes, he associated loss of self-respect and self- e, which seemed to give way to depression, ı, and dissatisfaction with the world in general. his aggression was centred on the employment , and much of it appeared unreasonable in view lp they were being offered. Among the men king work a few received small charity in the ld shillings from better-off relations.

parated, widowed, and single men leading a xistence could not give an account of the use leisure. Walking the streets was the only and acceptable explanation offered. A few were y seeking work but had such obvious and severe es that they could not persuade employers to hem: The zest for seeking work appeared ish with the length of unemployment. Unem- t appeared to lead to unemployment. Two e nearing their 65th year and old-age pensions ; premature ageing, together with poor physique, ng a serious effect on their prospects of employ- A common allegation made by the men over of 40 was that employers were not interested In 6 cases periods in the regular Armed Forces er been recovered from so far as resettlement was d. The attitude of the pensioner and the post- ation case in this group appears to resemble the persons with neurosis in receipt of public ce described by Lewis.[3] As regards a Hindu roup, colour seemed to contribute to his difficulty ining employment. Personality and mental excessive subsidy, physical disability, and age, order, were of importance in hindering return to

EDUCATIONAL RECORD

men had received more than a basic elementary on, 2 had attended grammar schools, 1 a central and 1 a night school for a year (the first year of his iceship, which was subsequently broken). Twenty ched the top standards of their schools, whereas not done well at school. The Indian had never school at all, 2 had been to special schools for defectives, 6 had attained standard 4 only, ard 5, 9 standard 6, and 5 standard 7 when the ndard was X7. Of these 26 who had not done school, 4 had had their schooling seriously pted by long spells of sickness, and 1 had had me family responsibilities at an early age on the of his parents.

BEHAVIOUR RECORD

r as could be ascertained, 5 men had served prison es ; 3 of these had had multiple convictions of including 1 who had also served a three-year at Borstal in his youth ; 2 others had had minor s preferred against them for theft, &c., and had short spells of imprisonment ; and 4 others ad bad military conduct records and had served s of detention in military barracks for desertion, rdination, &c.

MARITAL STATE

he whole group of 50 men there were 38 who had narried : 5 of the marriages were childless ; 7 men nly one child, and, at the other extreme, 1 had thirteen children, and 1 had ten ; 3 men had one mental defective child ; and the average number of children was four. Of the 38 men who had been married 12 had been either separated or divorced, but 1 of these had been happily remarried. Of the married men 22 were living with their families in rented accommodation, 3 widowers were living by themselves, and of the 12 separated or divorced men, apart from the 1 already mentioned, 2 had returned to their parents. 8 were living in lodgings, and 2 were living with female housekeepers. Of the 12 single men 3 were living in lodgings and 9 with grandparents, parents, or siblings. Much distress, unhappiness, and bitterness were associated with this picture : some of the separated men were having difficulty over separation allowances, one man was repeatedly being committed to jail for failure to pay maintenance allowance, and he and another seemed reluctant to take up employment because they would have to pay allowances to their wives and families if they did. Of the 12 separated men 2 had physical disabilities : 1 had tuberculosis ; 1 had very severe deafness with an associated anxiety state (he had written to several M.P.s and Cabinet Ministers about his unemployment) ; and in 10 the main disability appeared to be mental.

INTERESTS

Most of the men said they had no money for betting, football pools, cigarettes, beer, &c. A few had hobbies, mostly connected with their former work—e.g., radio repairs, and decorating. Four read (2 literature, 2 "wild westerns") ; and several were interested in horses and many more in football. In general, however, they showed lack of interest in life, poverty of thought, and absence of expression. Apart from a few with interests in families and the accomplishments of their children and grandchildren, few shared the satisfactions of life well described by Bakke [4] and more evident in the skilled than in the unskilled worker—i.e., the pride of being producers, of attachment to the personalities of employers, and the prestige of the wage packet, of club or union membership, or of hobbies and interests. Not one of these men owned his own house.

FOLLOW-UP

Two follow-ups have taken place, one six months and the other twelve months after the initial interviews. In the second it was found that 12 men had been placed in jobs by the employment exchange, 5 had found work for themselves ; and 1 man was being trained at a residential college for the severely disabled. Fifteen other men were not now signing the unemployment register for various reasons ; 2 had been transferred to other local offices ; 2 were receiving old-age pensions ; 1 was sick ; 3 were probably sick ; 3 were probably working on their own account ; 2 were wandering the country ; and there was no information about 2 others. Seventeen men were still, or again, signing the live register and remained unemployed ; 11 of them had worked for fourteen days or less, and most of them not at all, in the past year. Most of the men working had been very carefully placed in jobs specially canvassed for them by the resettlement officer with employers ; 3 men had been placed after courses of industrial rehabilitation. Many of those unemployed had had periods of sickness in the intervening period, and 1 man had had a further spell in prison.

CONCLUSIONS

Unemployment in the midst of full employment is the worst type of unemployment. Present unemployment is a medicosocial rather than an industrial problem. The unskilled man is the greatest sufferer, and the attitude of mind of the disabled man is the largest single factor in determining the prospects of future employment. By careful social occupational and medical assessment an accurate prognosis can be given. A third of these men can be restored to full employment, which brings with it well-marked improvement in physical and mental condition. A third are unemployable; they sign on regularly for work at employment exchanges, draw unemployment benefit, provide a depressing medicosocial and occupational problem, and handicap the work of the resettlement officer. The remaining third cannot be placed in any certain category.

---

[3] Lewis, A. *Lancet*, 1935, ii, 293.

[4] Bakke, E. W. The Unemployed Man. London, 1933.

Unemployed disabled persons are an equal burden to those operating the medical and social services and to employers. They are responsible for much wasteful changing of jobs. Many of these men are unsatisfactory and never likely to be permanently resettled. Practical assistance to the group can often be provided by a joint medical and social approach, but neither independently can hope to succeed. Recognition of the social state of the man and appreciation of his occupational and medical problems could lead to the institution of *prophylactic measures before complete disablement* supervened. Continued attendance for medical treatment and medical rehabilitation tends to emphasise disability, and removal from this atmosphere to one of more hopeful industrial rehabilitation, with the accent on remaining ability and concentration on recovery of self confidence, may be the most fruitful line of approach.

I am greatly indebted to the regional controller and other officers of the Ministry of Labour and National Service for making this survey possible, and to Dr. J. H. Twiston Davies for invaluable advice and criticism. The views expressed are personal; and the conclusions may not apply throughout the country.

INDOOR INVALID CHAIRS

FROM A CORRESPONDENT

Having had to use an invalid chair for three years, I *have some rather critical remarks to make on the* design and comfort of them.

I am 6 ft. tall, weigh about 12 st., and have rheumatoid arthritis, which affects most of my joints and is gradually getting worse. Movement is much limited in toes, ankles, knees (fixed in extension in plaster), hips, spine (gradually curving), shoulders (I cannot lift my elbows to shoulder level), elbows (now in acute state of pain and deformity), wrists, and fingers. The disease is now spreading to my neck and jaws, which are gradually becoming stiff.

MY PRESENT CHAIR

My present chair (fig. 1) is of the new tubular steel type, with large pneumatic wheels, at the side and two solid rubber castor wheels, leg-rest extensions, and a handle behind. I have had my handle removed after swiping ornaments from the window-ledges and removing paper from the wall. It stuck out too far.

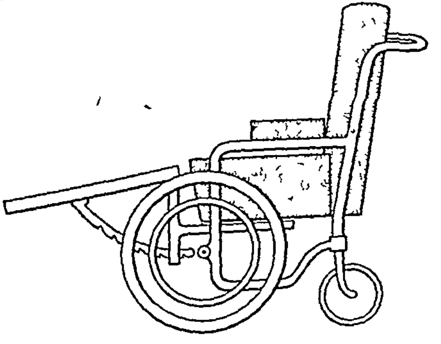

Fig. 1—The present chair, showing straight-back, no head-rest, arm-rests too short, no foot-rests, and no means of adjustment by the patient.

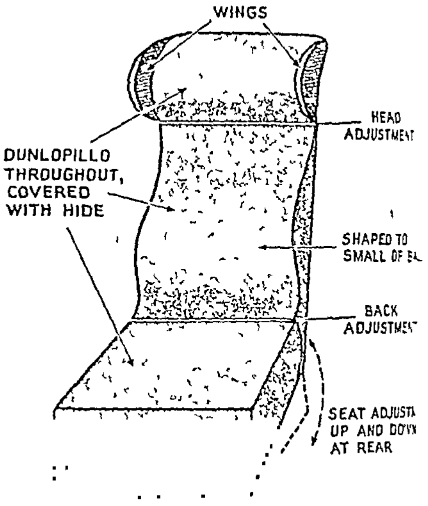
There is nothing about the movable parts of the chair that the patient can adjust. The back is straight but can be put at an angle by sliding the seat forward (only when unoccupied). The back is not high enough



WINGS
HEAD ADJUSTMEN
DUNLOPILLO THROUGHOUT, COVERED WITH HIDE
SHAPED TO SMALL OF B
BACK ADJUSTME
SEAT ADJUSTM UP AND DOW AT REAR

Fig. 2—Suggested seat and back-rest, showing shaped to head-rest, and adjustable seat.

and has no wings to rest against; so the pat no sleep. The leg-rests are adjustable for There are no foot-rests. Consequently, being st the patient gradually slides forward until hi bent and aching and his feet fall forward.

The seat has springs and is padded and cov cheap leather-cloth. You who have first cl try sitting on a similar seat with your legs st front of you (and without getting up to stret selves) from 11 A.M. to 10 P.M., eleven hours for one day only, not three years; then you will have some idea of what one has to go through. This is made *worse for me by the fact that* my elbows are too painful to help in taking the weight while I am trying to find a "softer spot."

The arm-rests are of 'Sorbo' rubber, gratifyingly soft but too high, too narrow, and too short. One sits with shoulders hunched and wrists hanging down over the ends instead of being supported. The distance between the rests is also too little, so the patient is forced *to sit in this* position because there is no room to drop his arms to his side.

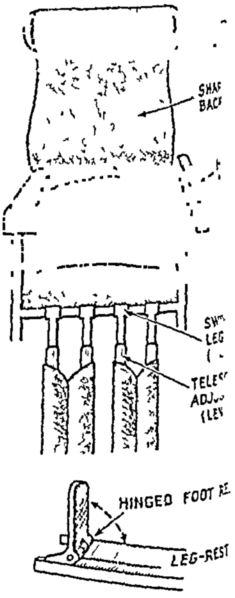


Fig. 3—Suggested hinged adjustable head-rest, foot-rests.

The tyres are pneumatic. When they are blown up hard, the ch delight to handle; but they lose air in two or thr which makes moving hard labour. If one tyre than the other, the chair rocks owing to its fa suspension. New valve rubber has to be fitted inflation, because it sticks and is finally blown off

These are some of the worst faults of my inval and to a person who is bound to use it per year after year, and is always in pain, surely it asking too much to have a little thought put design to enable the disabled to sit in comfort manipulate the adjustments to suit each ache when it occurs.

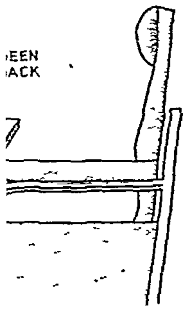
THE IDEAL CHAIR

-given much thought to my chair and its short- describe here what I think would be the ideal alid chair.

–This should be tubular, as at present, but of

—The side wheels should be pneumatic, and :heels small and solid, on castors. The large wheels should be puncture-proof, with ' valves.

ble Parts.—These should be easily worked from by the patient through a control wheel to the ıe chair, between the side-wheel and the frame. ·ol wheel would connect with a light four-way under the seat : (1) to adjust the angle of the (2) to adjust the telescopic leg-rest for length, ow it to fall to a perpendicular position in front of the seat to ease the entrance and exit of the patient; (3) to raise or lower the angle of the seat behind, because legs and seat must be in line; and (4) to adjust the back-rest from straight to reclining, or vice versa. The gear for each operation would be selected by a "gate" change, as on early motor-cars. If the gears were of low ratio, even the weakest patient could operate them. The patient puts the gear lever into he desires, turns the operating hand-wheel *is comfortable, and returns the gear lever* al. The adjustments could be carried out aulics as easily as, if not more easily than, ırs. The system would be the same as the ' jacking system in modern motor-cars. By urning a pointer to the desired operation and by handle the same results would be obtained.



gested adjustable table.

back.—This should be shaped, particularly nall of the back, and should be high enough for ent's head to rest against, and it should have ıgs at the top as an added rest (fig. 2). It should easily adjustable at the base for reclining or ıp. The whole back-rest should be made of illo' and covered with hide.

sts should be padded with dunlopillo covered and should be adjustable for angle and length, ged foot-rests of light alloy. They must also to fall perpendicularly in front of the seat, and wl all over the room when down, hindering both and exit of the chair. The padding of the :d only be from heel to calf, which would leave room for telescoping (fig. 3).

-This should be of dunlopillo covered in hide, tilted forward, and adjustable at the rear for ır lowering to keep the seat in line with the legs mes.

ests should be of square-section dunlopillo covered $3^{1}/_{2}$ in. square and 20–24 in. long, to give ample to the wrists. They should be hinged to open s (fig. 3), to allow the arm to rest by the patient's o be hung on arm-rests all day makes the elbows have removed the screws on my chair and the arm-rests for writing, &c. This gives me of elbow-room.

.—Fig. 4 shows a swivel table, strong enough a typewriter. Care should be taken to keep the low as possible, just clearing the legs ; otherwise ient's arms will ache through trying to hold them ıir.

HOSPITAL ESTIMATES

HOSPITAL authorities have received a Ministry of Health circular (R.H.B. [49] 117) indicating the basis on which their estimates for 1950–51 should be formulated.

MAINTENANCE EXPENDITURE

The Ministry asks that "in framing the estimates of maintenance expenditure for 1950–51 the strictest economy should be exercised and that provision should only be made for new services and the extension of existing services to such extent as the board considers to be urgently necessary and practicable."

In preparing the estimates, the provisions of the Nurses Bill, now before Parliament, are to be disregarded ; if this Bill is enacted, any necessary adjustment will be made when the revised estimates are prepared in the autumn of 1950.

CAPITAL EXPENDITURE

"The Minister" says the circular, "is investigating whether it will be possible, within the financial and productive resources that can be made available to the social services, to make available in the next few financial years a larger share for hospital works." To secure for urgently needed hospital developments "an adequate place" in the allocation of national resources, the Minister must have an outline programme of essential works for three years ahead.

Thus boards are asked to draw up their urgent capital-works programme for 1950–51 as part of an ordered programme extending over the years 1950–51, 1951–52, and 1952–53 : schemes of war-damage repair are to be specially indicated. The outline programmes for 1951–52 and 1952–53 should indicate as nearly as possible the principal development works likely to cost more than £10,000 ; a provisional figure for works under £10,000 should be included. Boards will not be held strictly to their outline programmes, but an early indication of their content, by enabling them to be discussed with the Ministry, will reduce the need for them to be examined when the time comes for formal submission. Boards are advised to draw up their schemes in such a way that if reduction proves necessary when the estimates for 1950–51 are considered, a portion of the work can be moved forward into the following year.

Capital Estimates for 1950–51.—Boards are asked to submit a list of capital works in three parts :

1. Works in progress at March 31, 1950, with expenditure falling in the year 1950–51.
2. Proposed works to be started in 1950–51, with the expenditure falling in that year and that required in later years to complete them.
3. Reserve list of essential works which should be started, if possible, in 1950–51, similarly divided as to expenditure for 1950–51 and later years.

In the case of regional boards, the total for (1) plus (2) should not exceed the total notified in March, 1949, for the year 1949–50 ; the total for (3) should be approximately 50% of the total of (1) and (2).

Boards of governors should submit similar lists, which "should be restricted to really urgent projects." In the case of London undergraduate hospitals and the provincial teaching hospitals, the total for (1) plus (2) should if possible be kept within the range of £50,000 to £100,000, and in the case of the London postgraduate hospitals within the range of £10,000 to £60,000. The total for (3) should normally not exceed one-third of the total for (1) and (2).

Outline Programmes for 1951–52 and 1952–53.—In the case of regional hospital boards the total for 1951–52, including the amounts to be carried forward if all projects for 1950–51 in lists (1), (2), and (3) are put in hand, should not exceed twice the total of (1) and (2); and the total for 1952–53 should not exceed three times that amount.

As regards boards of governors, “ the rate of capital expenditure on teaching hospitals during the past year or so has been proportionately much higher than at other hospitals ” ; and the outline programme should be kept within the same limits as those given for the capital estimates for 1950–51.

In addition, exceptional provision will, if possible, be made for starting one new major hospital project in 1951 and another in 1952. A list of projects is under consideration.

The circular emphasises “ that these figures represent the maximum which the Minister can hope to be allocated. . . . The actual amounts will depend on economic considerations and the needs of other social and industrial services and may well be substantially less.”

TERMS OF SERVICE FOR HOSPITAL STAFFS

The terms and conditions of service for hospital medical and dental staff[1] announced earlier this year have been clarified and slightly amended by the Ministry of Health in the light of questions brought to the Ministry's notice. The following are among the explanations and changes, which are given fully in a circular (R.H.B. [49] 115) to hospital authorities.

Young Consultants.—A doctor appointed as a consultant before the age of 30 should start at a salary of £1400 per annum, rising to £1550 per annum after one year's service, to £1700 per annum after two years' service, and thereafter in accordance with the scale for consultants appointed at age 32 or over. He should *not* remain on a salary of £1400 per annum until he reaches the age of 31. “ In effect, the salary scale for consultants is a continuous scale from a minimum of £1400 per annum to a maximum of £2750.

Senior Hospital Medical and Dental Officers.—The terms of service do not provide for the remuneration of senior hospital medical or dental officers below the age of 32, and it is not intended that anyone below this age shall hold such an appointment. “ Any officers below that age who have not been graded as consultants should therefore be graded as senior registrars, junior hospital medical officers, or general practitioners . . . as appropriate.”

Medical Superintendents and Deputies.—The terms of service laid down that remuneration of this group should be made up as follows :

> “ (1) For that fraction of their time given to clinical work, the same fraction of the whole-time salary of a consultant or senior hospital medical officer according to their grading ; plus
>
> (2) *for that fraction* of their time given to administrative work, the same fraction of the appropriate rate for hospital administrative staff.
>
> Where, however, a whole-time officer is engaged almost wholly in clinical work and gives only a small proportion of time to administrative duties, his appropriate clinical remuneration shall not be affected.”

It is now explained that the reference under (1) to the particular grades of consultant and senior hospital medical officer cannot override grading by a professional review committee ; and if a medical superintendent or deputy has been placed in some other grade the whole-time salary of that grade will be used for the purpose of the calculation under (1). The word “ &c ” should be inserted after “ senior hospital medical officer.”

Part-time Consultant Performing Teaching
The original terms stated :

> “ Consultants performing teaching duties con
> with, or separately from, their clinical wo
> remunerated by hospital boards like other
> (including distinction awards and expenses) in
> *any remuneration they may* receive from the un
> school in recognition of their teaching duties.”

The words “ or separately from ” and “
consultants ” are to be deleted, and the word
clinical work ” are to be inserted after “ remu
“ This expresses without ambiguity the original
Remuneration for teaching duties which are
from clinical work (e.g., lectures, tutorials, &c
responsibility not of the board but of the un
medical school. Such duties (as distinct from
during ward rounds, outpatient clinics, &c.)
considered to be ‘ clinical work ’ under the pa
and should therefore not be taken into accoun
pre-contract assessment . . . of the time required
duties attaching to the post.”

Membership of Medical Defence Societies—
understood that some hospital authorities hav
past required members of their medical staf
members of a medical defence society. The
sees no objection to the continuance of this prac

Medical Superintendents of Mental Inst
According to an earlier ruling (R.H.B. [49] 85),
puting the salary-rates of these officers, “ Boa
ignore any administrative duties of which the
impracticable to relieve a medical superintenden
these duties occupy only a small proportion
officer's time.” Now, however, the Ministry says

> “ Regional hospital boards will, of course, bear
> the importance of reducing to a minimum the t
> by the medical staff to administrative work. B
> should take into account the fact that the p
> medical superintendents in mental hospitals and
> deficiency institutions is affected by the requi
> Statutory Instrument, 1948, no. 419, under w
> medical superintendent's special position as chi
> necessitates his exercising a general control over al
> ments of the mental hospital or mental-deficiency
> tion. Moreover, much of the work which is
> regarded as administrative necessarily falls to the
> superintendent because it is essentially clinical in
> Under this heading would come the statutory
> work and the activities directly connected with the
> ment, training, and occupation of patients, as wel
> general supervision of entertainments and the pro
> amenities. As the medical superintendent is the
> whom any order of detention is addressed, the a
> for the general welfare of patients are his concern
> clinician and as an administrator. But the time
> purely administrative work need not, it is e
> exceed 10% of the time given by a whole-time o
> this may properly be regarded as so small a prop
> the time that there need be no abatement of the
> tion at clinical rates for the whole of his time.”

“ . . . We venerate leaders of the past precisely
they were courageous and farsighted enough to ch
concepts with new ones for a new age. . . . If history
strates anything it is that a frigid reception is us
accorded new social proposals. . . . It is interesting to c
attitudes in the physical and the social sciences. W
pride in the newest and most modern gadget or te
We are disturbed if the doctor evidences the slightest
tion that he is ‘ behind the times,’ since this may mean
suffering. But in social matters we are equally proud of
which were current when diseases were treated by bor
in the head. . . . It is true, as many maintain, that w
show a healthy skepticism toward new propositions
they have been proven. It is interesting to note, h
that those who advocate such experimental testing
concepts frequently do nothing to assist it and in fact
a great deal to prevent it.”—BRUCE STEWART,
Aug. 19, p. 179.

Education

FIRST MEDICAL EXAMINATION

Its Rôle in Selection of Students

M. L. JOHNSON
B.Sc., Ph.D.
EPARTMENT OF ANATOMY, UNIVERSITY COLLEGE,
LONDON

recent discussions on selection of medical omparatively little attention has been paid to medical (or exempting) examination. Pass or this examination obviously *does* select medical and a high failure-rate makes the selection In the London examinations there actually high failure-rate, which is causing concern plicants to medical schools and their teachers. ternal candidates for the London 1st M.B. in July, y 62 (13%) passed. Of 850 candidates taking a Higher School Certificate examination which empt them from 1st M.B. if they so desired *ing physics, chemistry, and either biology or* ad zoology), only 259 (30%) passed at a standard to allow them exemption.*

rength of the rôle of 1st M.B as a selector is ar at University College. London, where the of medical students obtain exemption from the before admission to the college (only between a a quarter are at present obtaining exemption ng the college's intermediate science course). ge's selection procedure is based on consideration pplicant's school record, and his performance at entrance examination and in an interview with ction board. Applicants for a place in the . class may be considered before they have he 1st M.B., and in that case may be offered a bject to their getting 1st M.B. exemption in time. 355 men applied for admission to the 2nd M.B. Among those applicants offered places by the board in the spring, 41 had not then got exemp- n the 1st M.B., and 18 of these subsequently failed n it. It is thus clear that selection by 1st M.B. is lifferently from selection by the board. In spite fact that selection by the board is very intense ection ratio being 1 in 7), more than one-third of didates considered suitable by the selection board ninated by the 1st M.B. A particularly striking discrepancy between the two criteria of selection t of a man whom the interviewing board regarded lectually the most outstanding man interviewed, o scored the third highest mark in the entrance ation, but who failed 1st M.B.

ral questions are raised by this extraordinarily ilure-rate:—Are so many candidates really not nough to pass? Is the syllabus too wide or too t? Is the examining too harsh?—I shall not t to discuss these questions here, but would draw on to two consequences of the failure-rate affect the selection and training of medical ts:

ome of the candidates who fail the 1st M.B. examination o not (for economic or other reasons) attempt it again nd are lost to medicine. Hence the *validity* of this nethod of selecting medical students should be inquired nto—i.e., to what extent performance in this examina- ion is predictive of performance as a doctor.

lany, however, repeat the course and the examination; nd it may be useful to consider the possible effects of his prolonged period of premedical study.

VALIDITY AS A SELECTING AGENT

It will be some years before we have data enabling us to relate the results of the London 1st M.B. to the student's later career. Meanwhile the experience of others is of interest. Gibson (1948) has shown that at Belfast performance in (internal) 1st M.B. examinations in 1942–43 was associated with performance in subsequent examinations: most of those students who completed the 1st M.B. examination at first attempt proceeded directly to qualification, whereas most of those completing the examination piecemeal failed again later in the course. In these conditions, therefore, selection on the basis of 1st M.B. performance would have increased efficiency of selection in the sense of decreasing the average amount of time spent on training a student. (As Gibson points out, it remains to be shown, of course, how performance as a student is correlated with performance as a doctor.) However, these findings cannot be extrapolated to the London candidates, who prepare for the examinations in various ways—in schools, technical colleges, or cram schools, or by private study. It is in fact rather unlikely that performance at these examinations, influenced as it must be by so many factors extraneous to the calibre of the candidate himself, will turn out to be predictive of subsequent performance as a doctor.

PROLONGING THE COURSE

Among the various factors affecting the selection of medical students, the 1st M.B. is peculiar in that it also forms part of the training for medicine. When the failure-rate in the examination is so high, serious repercussions on the functioning of the course in training may be expected.

The average amount of time now spent on getting 1st M.B. exemption is high. Of the 1948 2nd M.B. class at University College, London, 41 students had proceeded directly after School Certificate to attempt the 1st M.B. exemption (i.e., their education had not been interrupted by war service, education abroad, or otherwise): of these 41, 18 had achieved it within two years after School Certificate; 19, having failed at first attempt, had taken three years; and 4 had taken four years.

It is therefore pertinent to ask whether this time is profitably spent—i.e., whether students are getting the best possible training in premedical science. The effectiveness of the biological part of the training has been discussed elsewhere (Abercrombie and Johnson 1945, Bauer and Johnson 1946). The criticisms made apply, I believe, to the courses for London 1st M.B. and Higher School Certificate, and the deficiencies of the courses are likely to be accentuated by repetition. But there is another aspect of the failure-rate to which I want to draw attention here—namely, its psychological effect on students, which may influence their subsequent training.

The value of the premedical training to students must be measured by the extent to which the scientific principles it teaches become incorporated in their later study. Unfortunately, not a few medical graduates look back on their premedical course with impatience and distaste, partly because of its apparent irrelevance; and the hostility of present-day students is sharpened by fear of failure, which threatens their already slender chances of getting accepted by a medical school. Those who fail may repeat the course; many complete the examination piecemeal, spending dreary months on one or two recalcitrant subjects.

These would not seem the best conditions to foster the integration of the "fundamental sciences" with each other, or with the study of medicine. In designing curricula and determining the pass standard of examinations, the possible effects of these on learning capacity should be kept in mind. The deficiencies teachers com-

---

grateful to the External Registrar, the Examinations Depart- nt, and the Matriculation and School Examinations partment of the University of London for supplying this ormation.

plain of in their pupils—for instance, inability to observe or to reason—cannot safely be ascribed to stupidity or laziness and therefore dismissed as beyond control. It is more profitable to try to discover and remove those characteristics of the learning situation which strengthen non-rational resistances to the kind of training we think most desirable. Prominent among these is the anxiety which focuses on examinations, and which is naturally intensified if they seem to be unduly difficult.

This is not a plea for "lowering of standards": it is a plea for more searching consideration of the nature of *the standard. We should ask ourselves whether in fact* the best possible yardstick is being used to measure proficiency in premedical science; to what extent the proficiency so measured is predictive of performance in medicine; and to what extent the standard actually influences proficiency in medicine because of its significance in early training.

SUMMARY

SCHOOL OUTBREAK OF GASTRO-ENTERITIS ASSOCIATED WITH A PATHOGENIC PARACOLON BACILLUS

BETTY C. HOBBS
B.Sc., Ph.D. Lond., Dip.Bact.

MAIR E. M. THOMAS
B.Sc., M.B. Edin., D.P.H.

OF THE CENTRAL PUBLIC HEALTH LABORATORY, COLINDALE, LONDON

JOAN TAYLOR
B.Sc., M.B. Lond., D.P.H.

OF THE SALMONELLA REFERENCE LABORATORY, COLINDALE

IN September, 1947, an outbreak of gastro-enteritis affecting forty-seven out of three hundred children in an infant and junior school occurred 14–24 hours after a midday school meal. Of these forty-seven children, twenty-eight were acutely ill. They complained of headache and malaise followed by diarrhœa and vomiting some 4–24 hours later; in one patient the onset of diarrhœa was delayed for 48 hours. Pyrexia was present in some cases to 104°F, and persisted for a day or two. Collapse was reported in three patients. Most of the children had recovered after 48 hours of illness although some were unwell for 3–4 days and one child complained of malaise and diarrhœa for a longer period. A small number of cases occurred during the two days following the explosive outbreak, and the fathers of two of the children were reported ill with similar symptoms 2–3 days after the children. Although the onset was less acute in these patients the symptoms persisted slightly longer than in the children.

None of the sixteen members of the school staff or eight members of the kitchen staff, was affected. Within 3 hours of the report of the outbreak the school was visited, members of the staff were questioned, the kitchen was thoroughly inspected, and arrangements were made to visit patients to obtain specimens of fæces and vomit where possible.

INVESTIGATION OF PATIENTS

Twenty-four specimens of fæces and two specimens of vomit were obtained from patients 1–3 days after the outbreak, together with eight specimens of fæces from the kitchen staff. On desoxycholate citrate medium non-lactose-fermenting colonies of a uniform appearance, developing on some plates in almost pure culture, were isolated from fifteen of the fæcal specimens from patients and from one of the kitchen staff; these colonies failed to show slide agglutination with sera from any of the common members of the salmonella and dysentery groups.

Fermentation reactions after 24 hours suggested
organism was probably a paracolon bacillus,
subsequently referred to as paracolon 411
of the biochemical activities will be given in
section.

Coagulase-positive staphylococci were isolated
agar from fourteen specimens of fæces. There was
variety of types among these strains, but those
associated with staphylococcal enterotoxin food
described by Allison (1949) were not found. Sap
organisms only were isolated from the two spec
vomit.

Blood was taken from seven of the cases
days after the onset of symptoms, and the
tested for the presence of *agglutinins to the*
411. As a control twelve Wassermann sera we
at the same time. It will be seen from the
there was no difference in titre between sera from
and from the control group.

1 : 5–1 : 20 ..	0	Not tested	0
1 : 40–1 : 80 ..	0	2	6

INVESTIGATION OF FOOD

Information available about the foodstuffs
the day preceding the outbreak was as follows:

Pasteurised milk, common to the whole school, was
from the Express Dairy; *milk from the same* co
had been supplied to other schools without ill effect.

Most of the cases (38 out of 47) were in a group
children including infants and junior classes with a
from about 5 to 8 years. Their midday meal on the
question included cold tinned salmon, salad made
lettuce, beetroot, tomato, and cooked carrot, ser
salad cream made freshly from flour, vinegar, and
mashed potatoes, and freshly prepared sponge pud
tinned apricot jam.

In the nursery class of 43 children under 5 yea
there were 2 cases. Their meal consisted of hot fish
from the same batch of salmon mixed with potato
was baked in an oven for about half an hour and wa
to boil. It was served with a white sauce made with
flour. The same salad and salad cream were served
pie, and the same sponge pudding was given for
apricot jam being replaced by tinned orange jelly.

ining junior classes, about 100 children from 8 to 11 ate cheese, potato, and salad, followed by sponge d jam. None of these children was affected in the sive outbreak, but 7 of them were taken ill during ng 2 days.

embers of the school staff ate spaghetti and cheese, and salad cream, bread and margarine, and sponge ith jam, while the 8 members of the kitchen old salmon, salad and salad cream, and sponge ith jam. From these two groups no illness was

e seen that the salad and salad cream, potatoes, e pudding were eaten in common by the whole d that the foodstuff which appeared to be with the majority of cases was the tinned hirty-seven apparently normal one-pound tins used; eleven tins had been emptied into one sh and nineteen *into another*, while salmon o seven tins was used for the fish-pie. Preparahe meal were made at 10.30 A.M. and the dishes mon were refrigerated until 11.45 A.M., when covered and sent to the dining-hall.

vas no history of gastro-enteritis amongst the aff either before or during the outbreak, and ared to be free from cuts, abrasions, or other out the member found to be excreting paracolon e time of the outbreak continued to do so for after which her fæces were negative. The remises were clean and tidy and the washinglure and storage of crockery and utensils was ry.

BACTERIOLOGY

pecimens available for examination were remains almon from one large dish, six sound tins of rom the same batch, and thirty-seven empty ins taken from the dustbin approximately 24 er they had been thrown out.

ony count on the left-over portion of salmon was er g. at 37°C and 380,000 per g. at 22°C. Predominisms from direct and enrichment cultures were tic streptococci, *Staphylococcus albus*, and coliform rganisms of the salmonella and dysentery groups and positive staphylococci were not found. Strains of bacilli were isolated, but their biochemical and l reactions differed from the strain predominant in of most patients.

six unopened tins of salmon, three were incubated or 10 days and three were examined immediately. d enrichment cultures from all tins were sterile.

irty-seven empty tins were rinsed with quarter-Ringer solution and the suspensions were cultured and through liquid selective media for salmonella, , and paracolon bacilli. Organisms of the salmonella ntery groups were not found. Seventy or more of paracolon bacilli were examined, but their bio-and serological reactions differed from those of the ains.

ugh circumstantial evidence suggested that the might be the vehicle of infection there was no logical proof; the second dish of salmon may een infected, but none had been kept for tion.

possible that some other article of foodstuff such gredient of the salad may have been responsible. ne light of subsequent experience it seems likely infecting dose of the paracolon bacillus may be

ACTERIOLOGY OF THE PARACOLON BACILLUS

een strains of the paracolon bacillus were available study, of which seven were isolated from cases hœa in children, two on separate occasions from ber of the kitchen staff, three from two healthy volunteers who had swallowed cultures of the organism, one from a worker accidentally infected in the laboratory, and one from a sporadic case.

The organism was a gram-negative rod. A few motile forms were present, but fully motile cultures were isolated from each strain only after repeated passage through sloppy agar. On desoxycholate-citrate agar the colony was round and shiny, 2–3 mm. in diameter with an entire edge. All strains fermented glucose, maltose, mannitol, sorbitol, arabinose, xylose, and trehalose with the production of acid and gas after 24 hours' incubation, but failed to ferment sucrose, salicin, adonitol, rhamnose, and inositol after 21 days' incubation. All strains fermented lactose with the production of acid only at some time between 4 and 21 (usually 9) days; in addition they fermented dulcitol with the production of acid and gas between 1 and 13 (usually 3) days. Dextrin was fermented with the production of a small amount of acid after 24 hours' incubation. Indole was formed, citrate was not utilised. Urease and hydrogen sulphide were not formed, nor was gelatin liquefied. There was no change in the MacConkey broth after 48 hours' incubation at 44°C.

Serology

Antisera were prepared in rabbits using as inocula a suspension steamed for 2 hours for the production of anti-"O" serum and a suspension of a motile strain in broth killed with 0·3% formalin for the production of anti-"H" serum. It was thought that paracolon 411 might have a surface antigen comparable to those occurring in *Bacterium coli* described by Kauffman (1947). In addition, therefore, a serum was made by the intravenous inoculation of living culture. No evidence was obtained suggesting that these organisms had a surface antigen apart from the somatic antigen, since the titre of the serum made with the living inoculum was 1 : 1280 when tested with either a living or a steamed broth suspension, and absorption of this serum with the living or steamed suspension removed all agglutinins to the living suspension. It was found by direct titration and by agglutinin-absorption tests that all fourteen strains of paracolon 411 had the same somatic and flagellar antigens.

The biochemical reactions of paracolon 411 are very similar to those described for *Bact. coli* var. *acidi-lactici* and *Bact. coli mutabile*. Strains of these organisms were obtained from the National Collection of Type Cultures but were found to differ in their biochemical reactions and to have no serological relation to paracolon 411. All strains of the Arizona group of paracolon bacteria described by Edwards et al. (1947) were found to have no serological relation to paracolon 411. Paracolon organism type 29911 described by Stuart et al. (1946) was not agglutinated by the paracolon serum, but a serum made with type 29911, obtained from Dr. Wheeler, agglutinated the paracolon to 10% of the homologous titre.

Pathogenicity

Two drops of a young broth-culture of paracolon 411 were mixed with 5–6 ml. of quarter-strength Ringer solution. This mixture was introduced into the stomach of a monkey by means of a catheter. The monkey remained in good health with no signs of gastro-enteritis though the organism was recovered from the fæces over a period of several days.

Two human volunteers offered to test the pathogenicity of paracolon 411. Four drops of a 4-hour broth-culture of the organism were mixed with a portion of sterile tinned salmon. The portion was divided at once into two parts, each volunteer eating one.

About 22 hours after the ingestion of the infected salmon the first volunteer complained of slight abdominal discomfort. This was followed 2–3 hours later by shivering, pains in the limbs, and headache. The temperature at this time was 101°F, falling to normal within the following 48 hours. Nausea and diarrhœa started about 12 hours later. Diarrhœa was accompanied by upper abdominal pain which continued for a few days, particularly after the consumption of food. In the acute stage of the disease paracolon 411 was present in the fæces in almost pure culture. Three days later it was found in small numbers but was not isolated after 12 days when the patient had recovered.

The second volunteer began to feel unwell 3 days after eating the infected salmon. He complained of abdominal discomfort and lack of appetite for a few days. Paracolon 411 was isolated from specimens of fæces.

Specimens of blood taken before the ingestion of paracolon 411 and 4 weeks after, gave the following serological results when tested with a suspension of paracolon 411 :

Paracolon 411 suspension	1		2	
	Before	After	Before	After
H	<1 : 10	<1 : 10	<1 : 10	<1 : 10
O	<1 : 10	1 : 40	1 : 10	1 : 20

There is a definite rise in titre in the serum from the first volunteer though little change in the serum from the second.

While working with the paracolon a member of the laboratory staff became infected. The incubation period was about 48 hours and the clinical picture similar to that of the first volunteer. This patient's serum taken on the 5th day of disease failed to agglutinate the paracolon " O " suspension at a dilution of 1 : 10, but serum taken on the 20th day after onset agglutinated the suspension to a titre of 1 : 80.

DISCUSSION

The rôle of the paracolon group of organisms in diarrhœal conditions is very difficult to assess, for they are commonly found in specimens of fæces during the recovery period in patients who have been shown to be suffering from salmonella or dysentery infections.

Rhodes (1942) described a small outbreak of diarrhœa in a mental hospital associated with a paracolon bacillus differing from the present one in some of its biochemical reactions.

In the present investigation evidence pointed to paracolon 411 being the cause of the outbreak : cultures from fæces in the acute phase of the disease showed it in almost pure culture ; it disappeared from the fæces with the recovery of the patient ; and it was isolated from the majority of specimens of fæces received during the acute stage of the disease. Careful investigation of some of the articles of food left over from the suspected meal failed to reveal paracolon 411. Other foods—notably fresh salad, salad cream, fish pie, and one dish of cold salmon—were not investigated, because none remained, and it is possible that one or more of these foods may have been the vehicle of infection. It seems unlikely that the paracolon was present as a contaminant due to faulty processing in an unopened tin of salmon : it is far more likely that one or other of the foodstuffs eaten at the meal was infected accidentally. But no data as to the source of the infecting organism were obtained ; for the food-handler found to be excreting the organism over a period of some weeks may herself have been infected in the kitchen.

The infecting dose of paracolon 411 may be assumed to be small, since the period between the preparation and consumption of the foods was about $1^1/_2$ hours which would not allow time for a large increase in the number of bacteria present.

Proof of pathogenicity was provided by two human volunteers and an accidental case of laboratory infection. The two human volunteers were infected by the consumption of probably not more than 500,0 —a small infecting dose when compared with t of 2000–4000 million *Salmonella typhi-mur* Hormaeche et al. (1936) found necessary for the of human volunteers. Additional evidence of inf a significant rise in agglutinin titres in the se of the patients during convalescence.

It may be mentioned that one of us (J. T.) thirteen strains of a paracolon bacillus isolated outbreak of food-poisoning in a prisoner-of-war Leicestershire and two sporadic cases of gastro —one in Hull and the other in Oxford. The reactions of these strains were the same as paracolon 411 described except that all thirte small amount of acid, or acid and gas, in 1–7 days, and acid and gas in MacConkey 48 hours' incubation at 44°C. Ten of the were firmly non-motile, but after many became motile. A serum was made using one of reciprocal absorption tests showed that these were serologically identical with paracolon 411.

SUMMARY

In an outbreak of food-poisoning among children, a serologically homogeneous strain of colon bacillus was isolated from the ma patients.

This organism produced illness in two huma teers, and also by an accidental laboratory infe

The infecting organism was not found in foods examined.

From a knowledge of the methods of the pr of the food in this outbreak, and from the organisms causing infection in the two volu appears that comparatively small numbers of th of paracolon bacillus can produce illness.

We wish to thank Dr. W. C. Harvey, medical officer for making arrangements for the visiting of pa promptly after the onset of symptoms. The collection specimens and epidemiological data at an early sta possible to obtain a clear picture of the outbreak wish to thank Dr. H. J. Harris for his valuable a and Dr. R. Pilsworth for sending strains from the o Leicestershire. The strain has been deposited in the collection of Type Cultures, and bears the number

Poliomyelitis

In the week ended Sept. 3 notifications in E and Wales were : poliomyelitis 289 (258), polioe litis 19 (22). Figures for the previous week are in *parentheses*.

The following counties reported multiple London 43 (34), Berkshire 5 (3), Chester 3 (0), C 5 (5), Cumberland 1 (1), Derby 2 (2), Devon Dorset 2 (2), Durham 8 (3), Essex 21 (13), Gl 13 (14), Hertford 3 (6), Huntingdon 2 (0), Kent Lancaster 28 (33), Leicester 11 (1), Lincs, Kesten- Lincs, Lindsey 5 (3), Middlesex 18 (17), North 3 (4), Northumberland 10 (6), Nottingham Somerset 9 (6), Southampton 10 (16), Stafford Suffolk, East 2 (1), Surrey 7 (5), Sussex, Ea Sussex, West 3 (2), Warwick 8 (7), Wiltshire Worcester 4 (0), Yorks, West Riding 37 (33), Gla- 5 (1).

The fluctuation during the past three week thought to have any special significance ; and th increase in the weekly total should not be tak omen of further rises of considerable magnitude

Disabilities

CHRONIC MYELOID LEUKÆMIA

I was 51. Life has always been a mad rush
il these last few years have slowed me down.
onder whether the violent sport I undertook
th was detrimental to my health. I have had
, too. even though I prided myself on doing
ly and in the best manner. I pulled my side
mping, I remember, when gaining the school
hip—quite an achievement in those days,
t lady-like. In fact, now that I think about it,
d trouble with my side for many years. For
lying in bed on my left side has for a long
very uncomfortable.

1946–47, when I was 48–49, I began to feel
d the pain in my side was getting naggingly
ly doctor could find nothing wrong with me
sted my age and fibrositis as the cause of my
s. My weight was noticeably diminishing and
became anxious. All this time I carried on as
ting up at 7.15 A.M. and dragging myself about
hold duties, though I often had to stop in the
a job, flop on my bed, and go fast asleep for short
most unusual for me. I lost three stone in a year.
tor ordered me extra milk and took a sugar
ere was a small amount present, so I went to
or a full test. I also had my chest examined
s. These proved to be all clear and the clinic
ympathetically told me I was suffering from
exhaustion due to the menopause. The meno-
y the way, I got over quite without trouble.
while on holiday with my family, which I spent
out, that I discovered the lump in my side.
as I returned home my doctor examined me and
t it was my spleen and I would have to have
sts. I went to a special clinic, where a blood-
as taken and I underwent the most thorough
tion I have yet experienced. I was told I was
from myeloid leukæmia and was advised to
ections of nitrogen mustard as soon as possible.
arned that these would be unpleasant and make
ill. They did—but I know I would not be alive
ut for them. I was in such a low state that
ed a hospital for treatment and observation.
ood tests were done daily and I began to take
sulphate and ascorbic acid, and I had the injec-
ery four days. After five injections my white-cell
ropped from 552,000 to 21,200. After this I had
r ten weeks. Then I started the injections again,
es fortnightly, sometimes monthly.

injection was usually given about 3 or 4 P.M.
that I had two hours' grace before the sickness
My aim was to go to bed and try to sleep, and for
took a sedative. I found a mild one (pheno-
ne) preferable to hyoscine as I felt more normal
rds. I was sick for four hours, at 15-minute
ls, the actual vomiting lasting a few minutes each
The retching and straining distressed me very much
t me extremely exhausted, but at the end of the
urs I would fall asleep. It helped greatly to have
by me to cheer myself up with " Half way now,"
nly another hour now."

t day I found it was best to stay in bed until mid-
g. I would take breakfast and feel cheered to
e worst over. I felt quite well on getting up—
shaken perhaps, since even an ordinary bilious
has always proved a major calamity for me.
I had been up a short while I would begin to feel
shaky and slightly nauseated. To get up very
y from a chair would produce a feeling of being
d-out, and it took three days before I felt better.
ps a younger person would have more resistance.

I dreaded the injections terribly, yet I would go of my own accord before my next appointment and ask for one, if I thought my count was getting high, since they had such marvellous and immediate results. Incidentally, I can tell what my count is doing from the size of my spleen. It disappears at about 16,000–18,000 and I can make a good guess up to 50,000 or 60,000: over that I just know it is very high.

After having injections at various intervals for about four months I began to put on weight, and after six months nobody would have guessed there was anything wrong with me, though I think my weight fluctuates a little. I carried on with this treatment, visiting my specialist for spleen examinations and blood-counts, with injections accordingly, for about a year, when to my joy one day I was told a new treatment was to be tried, consisting of a similar drug in tablet form.*

* * *

Now, the injections definitely haunted me. Frankly, I was afraid of them, though I knew they were keeping me alive. I sometimes wondered how I could go on living if I had to have them. They say that nausea can cure a drunk, the feeling is so awful; so it will be understood how one feels about the sickness. My family had to be considerate to me during these bouts, and it worried me to be a liability to them, though I cannot say enough for the wonderful patience, understanding, and moral support I received from my husband even when I was told nothing was wrong with me. This is extremely important to a woman. The doctors can do much, but unless the patient's morale is high they must be handicapped. So the injections were a shadow, even though I kept congratulating myself on being able to have any treatment at all.

At first I was dubious about the pills. I wondered whether they would produce the same awful effects. but so far I have been fortunate. Four pills affect the bladder sufficiently to be slightly uncomfortable. Three pills let me know they are working and cut my count by half in two weeks. I notice they take about 8–10 days to start working. This is a pity sometimes, as the count in the meantime is soaring. My doctor is now aiming to find how many pills are needed to keep me on an even keel. At the moment I am on $1^1/_2$ daily. My red cells and hæmoglobin vary, I suppose according to the energy I expend, and mental worry I think also affects them. 'Metatone' cheers me up wonderfully, and a glass of burgundy—I like to think—is excellent. But the pill treatment is so mild that I do not consider myself an invalid any longer. Indeed, most of the time I completely forget my complaint. I can walk to and from the village—2 miles altogether—when I am in good form, which is quite often, and arrive home fresh and ready to prepare whatever meal is due. I go and spend a week in London and do a day's shopping in town. I enjoy life, though perhaps I am more sedate than I used to be. I live quietly, which is no punishment, and rest if I feel I need it. The only alteration in my mode of living is that I have given up cycling—loading my bike up with shopping parcels and string bags full of vegetables is too much for me. I am poor at standing, so I just don't stand. I find a seat anywhere. I get weary sometimes—perhaps if my count has been high; but every mother seems to be weary these days.

My doctor has always treated me frankly, teaching me about my malady and giving me credit for a little intelligence, and this has encouraged me to coöperate.

If the injections can be avoided, leukæmia is not a bad disease really—no pain, one can eat what one likes, and do anything one feels up to, and one has a legitimate excuse for being lazy. I bear this in mind and am thankful.

* We understand that results of clinical trials with this drug have not yet been published, and that other patients have seldom had such benefit from it as our contributor records.—ED. L.

In England Now

A Running Commentary by Peripatetic Correspondents

MY holiday this summer presented me with a valuable addition to my therapeutic armamentarium. The Western Highlands had drawn me for the fishing, but rivers were low and water and skies clear. Even the sea lochs failed, for as the local fisherman had it "the fish had a' stravaiged awa on their ain mysteerious occasions." Not being fit enough to climb mountains I loafed around—a thing my temperament allows only for a short period. One evening a chance remark led to an impromptu exhibition of water-colour sketches in the hotel lounge. The artists were all amateurs and enthusiasts. Four members of the Ayrshire Sketching Club had come north to paint. The other two exhibitors, a pharmacist and a physician from London, were sketching as an incidental to the holiday. The pictures took my eye at once. There were about 40 water-colours, all attractive, some strikingly beautiful. The number impressed me, for it was a surprise that all these fine sketches had been done in less than ten days.

"I paint for pleasure of painting," the physician admitted. "My efforts will never be hung even in the decent privacy of my dressing-room. They will sleep in a portfolio and I may hardly look at them again—except for self-discipline," he added ruefully. He waved aside my complimentary objections. "No," he went on, "I know my own limitations. But I like painting and there is no other occupation I know which is so rewarding to the incompetent. But it has done more than give me pleasure, for it prevented an incipient nervous breakdown a couple of years ago. A colleague prescribed paint brushes for me and I've blessed him many times since." He eyed me with that unmistakable look of clinical appraisal. "And if I may suggest it, my friend, it is a prescription you could profitably take yourself. If you like I will lend you paints and things tomorrow."

Next day my colleague reminded me of Mr. Churchill's advice to be bold and resolute, and then left me to it. My previous experience of drawing was meagre—though I recall that Sharpey-Schafer once almost praised my histology notebook. But I took a big wet brush and slapped the paper full in the face. For a moment I felt I had been too temerarious, but anxiety disappeared with every daub, and soon I was slashing on rich, rewarding colour with gusto. For the rest of the holiday I did not repine over the low water in the river. Since I returned to my practice I have gone on painting and I am calmer and happier than I have been for years, because of the relaxation given by this beautiful hobby. And it is beautiful even though perhaps all my paintings are not. Anyway I have put several patients on it and they have all benefited. This therapy has the advantage of being quite safe, and it appears virtually impossible to overdose.

* * *

We have all read about the surgeon who admits his dying fiancée to the casualty department or who finds himself amputating his wife's leg. But have you tried being on duty for yourself? In my small hospital we take some pride in having maintained a 24-hour X-ray service (the radiographer and myself) for over twenty years. It was, of course, during my spell of duty that I fell heavily from a stage and assessed the damage as a badly bruised right hip, an almost useless right arm with no power of adduction, and a minimum certainty of a subcoracoid dislocation of the head of the right humerus. It seemed all important to get a skiagram before the rapidly increasing pain from arterial and muscle spasm produced complete incapacity. My new car, with its gear-change on the steering column, requires at least some power in one's right hand, but with the help of a kind friend from the audience I managed to park the car at the hospital and hobble along to the X-ray department, only to find that increasing pain and faintness made any practical movements impossible. Night sister arrived at once and made things harder still. Though hitherto our slightest word had been law, now all was changed. We were now a patient, and patients didn't treat themselves in a properly run hospital. She flew to telephone my partner and the rad Meanwhile, feeling certain that the latter w unobtainable and that the sands of time wer out as the hand became more ischæmic, I m persuade the young and kindly nurse who was me to pull over and switch on a portable di while I struggled into a half-lying position on X-ray table. Night sister soon returned to matron was dressing. With reluctant appre the circumstances, sister helped to push a cas the damaged shoulder, and the two girls betw as if they were handling red hot devils, aligned and set the time switch to my mumbled direct nose in pillow.

I was just able to stagger into the change the film left-handed from the cassette to and into the waiting developing tank. Then mental seconds for development time—this is of a distraction against pain—I made a final dumped the film into hypo. Then I fell almost arms of my partner and very gratefully left th conduct of affairs to him. Matron had now keep order and tell me that one of my surgical *was on his way. Meanwhile she* supported paralysed arm while my partner lifted out film and found a viewing screen within my field I had underestimated development time wit developer—it was now 11 P.M.—but the film clear subcoracoid dislocation and, more no obvious fracture. Then my fellow surgeon to make a careful examination, characteristically to see the film until he had made a clinical After that, along came an injection of anæsthetic, and expert reduction.

One has to be a patient oneself to realise the value of confidence in one's surgeon and and how ghastly it would be to have to sub operation without that confidence. After a very able night in a private ward I won two pitched one with a young nurse determined to give me a bath (perhaps because I had taken out her appe months before) and the other with the entire staff, now abetted by my dear wife, who idea of dressing and going home. Two day except for a sling, there was surprisingly little d True, I could only play the church organ left and it was not very kind of the congregation to they didn't notice any difference.

* * *

Having been used to a teeming outpatient in a Chinese city, doing a locum tenens in th country" is a bit of a change. There it was m than not: "What kind of a pain?" "Where pain start?" "Was it relieved by meals?" all ing to the Teachers. Here it is: "What colour medicine?" "Did you take it twice or three day?" "Did it make you sleepy?" This after a search through the records, ending in a ring to the local chemist for the magic mixture which Mrs. X will not be able to endure day.

There the patient could be seen returning hom *many miles distant), walking carefully between* th gingerly holding a three-ounce bottle suspended neck with string. Here nothing less than a ounce bottle will do, even for the patient in th street.

Here, given the immense advantage of being address the patient in one's native tongue, I the temerity one day to take the bull by th and suggest that that pain of indefinite charac obvious psychogenic origin was not due to any able disorder of the stomach but to an anxious of the mind—following the methods of explanati reassurance advocated by the Teachers when by an anxiety state. By the end of the day, b after repeated visits and angry parleys with the vexed friends and relations, I heartily wished back in China with the limitations of that tongue to restrain any sorties into the too too fields of psychological medicine, as the well-love rhei co. was once more offered to appease the angered psyche and pander to his *aerophagic* hab

PAYMENT FOR INVOLUNTARY RESIDENCE IN HOSPITAL

SIR,—The salaries of hospital doctors are now assessed to exclude residence; and suitable sums for residence are to be deducted where necessary.

If a doctor is fully resident he uses the hospital as his hotel and a full deduction seems appropriate. But many registrars are resident only when on duty. Residence then becomes an imposition, of value to the employer, and the doctor ought really to be paid extra for it. The L.C.C. recognised this principle in allowing assistant medical officers to be non-resident and granting full non-resident allowance, although the doctor was usually expected to live in when on duty.

Some management committees appear to be intending to charge these unfortunate residents-on-duty for part or even full residence costs. Some of these men are quite senior and their residence is of very obvious advantage to their hospitals. All have their home expenses and all must pay income-tax on their whole salary, including the sum deducted at source for residence. It is much to be hoped that medical members of management committees will resist any attempts to deduct from an employee's salary in respect of his overtime.

London, E.11. J. BARNARD.

SODIUM β-GLYCEROPHOSPHATE IN OBSTETRICS

SIR,—Since 1946 many papers have appeared in the Spanish and South American journals extolling the virtues of sodium β-glycerophosphate in the treatment of abortion and disorders of uterine activity. Velazquez and his colleagues[1] and Cativiela[2] have examined its pharmacological properties and regard it as a non-toxic and effective antispasmodic of smooth muscle. There have been very favourable reports of its effect in threatened abortion, hypertonia of the uterus, and persistent afterpains.[2 3]

In view of this, the drug was given a short trial here. Some difficulty was experienced in preparing the solution for intravenous injection, a 50% solution having been recommended but no details for preparation given. A 50% solution of sodium β-glycerophosphate *B.P.C.* was prepared in sterile water and resterilised in 10 ml. ampoules at 115°C for 30 minutes.

Altogether twenty cases of threatened abortion were treated by rest in bed and intravenous injection of this solution. The dosage varied considerably—from 10 ml. per day (as recommended) to 10 ml. whenever uterine contractions were apparent; 16 cases received considerably more of the substance than has been reported in the original papers. In all the cases the cervix was closed at the commencement of therapy, and every case aborted within five days; no toxic effects were noted. In view of these poor results, no extended trial has been made of its effect on the full-term uterus. However, in 2 cases injections of 10 ml. of the solution were given during apparently normal first stages of labour when contractions were well established and the cervix four-fingers dilated; no diminution in the frequency and strength of the contractions was noted and further doses produced no effect. In one case, 30 ml. was given well on in the second stage; no effect whatsoever was observed.

In our hands, therefore, the substance appears to be ineffective in diminishing uterine tone. None of the patients gave any history suggestive of vitamin-B deficiency, the commonest cause of failure reported in

2. Cativiela, M. R. *Farmacoterap. actual*, 1946, 3, 474; *Ibid*, 1947, 4, 26.
3. Llusia, J. B., Funcasta, C. G. *Obstet. ginec. latino-amer.* 1946, 4, 896. Santamaria, L. T. *Hisp. Med.* 1946, 3, 481.

the original papers. This *B.P.C.* grade of sodium β-glycerophosphate does contain a little of the α form, but Velazquez states that this too is effective. The possibility that the substance decomposes on autoclaving has also been investigated, but it appears to be stable.

The unavoidable conclusion is, therefore, that sodium β-glycerophosphate is of no use in the treatment of abortion and has no effect on the contracting full-term uterus.

Senior Registrar.

PERFORATION OF INTESTINE BY FISH-BONE

SIR,—Mr. Travers's article last week calls to my mind a similar case operated on by me.

For six weeks before consulting me in December, 1944, the patient, a stout elderly man, had persistent pain in the abdomen followed by a swelling immediately to the right of the umbilicus. This swelling had diminished and then reappeared. He had a very deep umbilicus, and I concluded that the swelling was due to cellulitis with suppuration in an hour-glass umbilicus.

Appropriate treatment was ordered and I did not see him again until June, 1945, when there was an obvious abscess in the same situation. Immediately before incising this, I ventured a guess that a foreign body might be present. A small amount of pus was evacuated, and, on exploring the cavity with a finger, the foreign body, which was a flat and springy fish-bone $^1/_8$ in. wide and 1 in. long, was removed. The wound healed normally.

Obviously this bone must have perforated the small intestine, causing the abdominal pain of which the patient complained, and had managed to perforate the peritoneum and fasciæ. The patient had no recollection of having swallowed this bone.

Plymouth. EDRIC WILSON.

CONCENTRATION OF DIPHTHERIA ANTITOXIN IN CORD BLOOD

SIR,—I was interested in the article by Miss Barr, Mr. Glenny, and Dr. Randall in your issue of Aug. 20.

For reasons pointed out elsewhere[1] one may assume that diphtheria antitoxin is a univalent antibody, and that therefore its concentration in the cord serum and the maternal serum should be equal. In fact, the data given by Miss Barr and her colleagues in table II fulfil this expectation. In their conclusion, however, the authors state: "The antitoxin content of cord blood was very appreciably higher than that of antenatal samples of the mother's blood taken during labour."

The reason for the discrepancy between the conclusion and the actual findings can be found in the body of the article, where the authors claim that the method of titrating antitoxin used by them has an error of less than 10%. Actually, serological titrations ordinarily have a minimum error of about 100%, and only by doing multiple titrations and averaging the results can the error be reduced to 50%. If the authors' conclusions were correct, then it should be possible to take the same samples blind—that is, with no indication of which is the cord blood and which is the maternal blood —and by repeating the titrations to identify the samples correctly. Had this experiment been tried by the authors they would have found that they could not really differentiate the cord serum from the maternal serum, showing that the titres of antitoxin in the cord serum and the maternal serum are not significantly different. In five cases where the antitoxin titrations were repeated on the baby's serum only 1–5 days after birth, lower titres were obtained which agreed more closely with the maternal titres, demonstrating the existence of a relatively large experimental error.

ecause it is concerned essentially with the pre-
of the patterns of disease and with hygiene.
sent general practice is not being well taught
graduates or undergraduates—at least, as a
discipline. Its condition calls, I believe, for a
on of inquiry.

er. HOWARD E. COLLIER.

The true answer to the above question can be
Dr. D. R. Goodfellow's "Reflections on leaving
Practice," published in Bulletin no. 5 of the
ip for Freedom in Medicine. I shall be happy
n a copy to anyone interested.

On reading this very human document two thoughts struck me forcibly. Firstly, unlike so many of us, the writer actually welcomed the National Health scheme and determined to try to make it a success. Secondly, the writer is so obviously sincere. It is a tale of disillusion and frustration, and should be read by everyone before others can make the same mistake. I am glad to see that Dr. Goodfellow stresses the impossibility of treating anything like 4000 patients, and of course it is nonsense for men to say that they can effectually do so. They may be able to "manage" them, with the help of dispensers, but this is not real doctoring nor medicine. In over 25 years of general practice I saw how big panel practices were run or managed ; the choice of word is immaterial.

I can reassure Dr. Goodfellow that there is nothing cowardly in resigning from impossible conditions of service. It is the advice any doctor who can think clearly will give his own son today. Undoubtedly it will further Mr. Aneurin Bevan's purpose in levelling down the profession, but the time will come, in general practice at any rate, when most men worthy of the name of doctor will be *outside* his health service of today.

No ; the word cowardly might be more fittingly applied to those who led the profession into such a mess, and this does not absolve the highest, nor the lowest. Rather I congratulate Dr. Goodfellow in his courage, and I hope everyone will read his reflections, and we may then be spared such effusions as "the sympathetic attitude of the Minister of Health."

Hampstead, London, N.W.3. H. V. DEAKIN.

NATIONAL COAL BOARD

SIR,—In his letter last week Dr. Capel rightly draws attention to the notable developments in the field of health brought about by the National Coal Board. Nevertheless, he is hardly fair to private enterprise in saying that the first seeds of a medical service in the coalmining industry were sown by the Ministry of Fuel and Power. Progressive mine-owners established medical treatment centres at their collieries more than twenty years ago.

Codnor, Derbyshire G. F. KEATINGE.

CANICOLA FEVER

SIR,—It has been suggested to me that case 4 recorded by Captain Watts and myself in our paper of May 28 was one not of canicola fever but of leptospirosis icterohæmorrhagiæ. The reasons for this suggestion were : (1) that jaundice and pneumonia are unusual in canicola fever, and (2) that the symptoms in the patient's two dogs were unusual for a leptospiral infection.

The full serological findings in this case (omitted from our abbreviated report) were :

Day of disease	*L. canicola*	*L. icterohæmorrhagiæ*
7	+ at 1/100	+ at 1/10
	± at 1/3000	± at 1/30
	± at 1/1000	
16	− at 1/1000	− at 1/1000
31	+ at 1/1000	− at 1/100
	trace at 1/3000	trace at 1/300
79	+ at 1/1000	+ at 1/10
		trace at 1/30
140	+ at 1/300	− at 1/10

Though jaundice and pulmonary infiltration are admittedly rare in canicola fever, they nevertheless occur ; for example, cases showing both these conditions have lately been reported by Günther-Kühne and others.[1] The serological results in our case leave no doubt, I believe, that our diagnosis was correct.

Military Hospital, Cowglen,
Glasgow. JOHN MACKAY-DICK.

ANURIA FOLLOWING ISCHÆMIA OF RENAL CORTEX

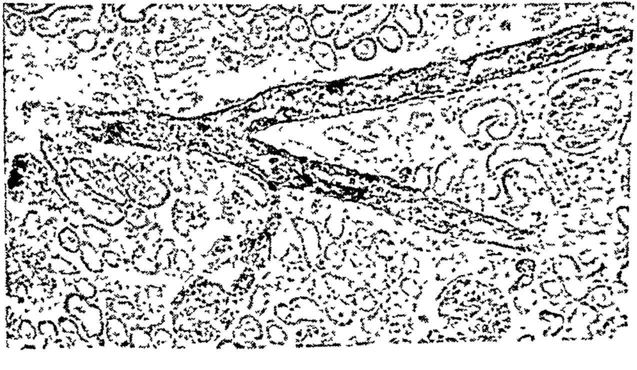
SIR,—In his article of June 4, Dr. Solymoss mentions Furtwaengler [1] as having suggested thrombosis or spasm of renal vessels as the ætiological factor in symmetrical cortical necrosis.

It is interesting to recall that in 1911 Professor Teacher,[2] of Glasgow, wrote of cortical necrosis:

> "It is an anæmic necrosis or infarction affecting about two-thirds of the whole renal cortex in both kidneys, and it is caused by thrombosis in the interlobular arteries, the peculiar distribution of which is best explained on the theory of spasmodic contraction affecting these arteries and so favouring the formation of localized thrombus."

He also considered the hepatic lesions of eclampsia as being of the nature of infarcts. As early as 1906 Professor Jardine,[3] of Glasgow, quoted Teacher's opinion that the renal lesion is essentially an infarction, and he provided a beautiful coloured illustration, by A. K. Maxwell, of confluent infarction. In 1911 Jardine and Teacher [4] published contrasting illustrations of cortical necrosis, diffuse and focal, in eclampsia. To the naked eye the lesions encountered are sometimes more correctly described as confluent infarcts than as symmetrical necrosis, and indeed for many years the professor of pathology at Glasgow illustrated his lecture on infarction with one of Teacher's specimens. The specimen is illustrated in Muir's *Textbook of Pathology*.[5]

Dr. Solymoss appears to consider that the medullary shunt plays an active part in the lesion. In 1947 I illustrated in Bristol a postgraduate lecture on eclampsia with kidneys from the condition. In one case both cortex and medulla showed extreme pallor; histology revealed nothing but lack of blood. In another case the cortex was extremely pale; the medulla was deeply congested, but there was no histological abnormality except that the interlobular arteries were dilated and the medullary vessels stuffed with blood. A third was similar except that there was early necrosis of all structures in the outer two-thirds of the cortex. A fourth showed the classical picture of cortical necrosis. From these cases, and referring to the cases of confluent infarction, I concluded that the medullary shunt merely played a passive rôle. Where the spasm was localised to the interlobulars, the blood in the renal arteries was merely diverted to the medulla. In the case where the kidneys showed blanching of cortex and medulla, I considered that the spasm must have been in the renal arteries.



The accompanying illustration is of renal cortical necrosis where the patient lived for some days in coma; I conclude that spasm has been sufficiently prolonged and severe to lead to devitalisation of the cortex. On relaxation of the spasm, blood has rushed into tissue. The interlobular artery and afferent are enormously dilated and lined by mural. Many glomerulur capillaries are dilated and blood. On the other hand, where the spasm is duration or is sufficiently intermittent, no abnormality may be found in the cortex.

Shaw Dunn and Montgomery [6] conclude vascular abnormality in cortical necrosis in the glomerulus and works back to the arteries. This theory is difficult to Teacher's specimens of multiple infarction point to a prime abnormality in the vessels the infarcted areas—the interlobulars. De Nav considers that the primary abnormality is nec interlobular arteries. This theory falls down can lay out a series of kidneys from cases of and show that necrosis is one end of a scale at end of which are kidneys which yield pathologist except a peculiar distribution Certainly the interlobulars may at times be but this is an end-result; before this there functional abnormality—presumably spasm. shown healed lesions of eclampsia in the vessels. De Navasquez's condition would invariably fatal; eclampsia is not.

Much confusion has been caused by writers to the liver necrosis as zonal. While micro it is especially periportal in distribution, of the liver will show large blotchy areas of irregular in size and shape, and scattered th the liver substance. I agree with Teacher that essentially infarctive and, finding no thrombi, I that they are due to spasm of the hepatic art

To anyone who peruses the British liter eclampsia it will be apparent that Teacher's been completely neglected and that our naked-eye pathology have declined.

HOSPITAL POSTS FOR THE MIDDLE

SIR,—Of those in difficulties through the intr of the National Health Service, one group seems escaped notice—namely, that of the mid specialists who, for one reason or another, attached to a hospital or clinic at the start service.

I do not know whether we are a large or a sma but I do know a number of others in the same myself. We are too old to try for junior appointments, especially of the residential kind, appointments are almost always made—and ju so—by promotion from the lower ranks; while posts are being created into which we might fit, a sessional or part-time basis.

Here the trouble seems to lie. Obviously the for specialist services cannot have diminished; there are constant complaints of shortage of staff. Yet no arrangements are being made to those who, like myself, have found their priva very much curtailed by the service and the shortage of money, and are competent and take on hospital work, given anything like conditions.

Granted that some of those not employed are unemployable, there are still some of us who ha nothing worse, professionally, than to work in hospitals or clinics, or in private practice, rat attach ourselves in time to institutions taken ov Ministry.

IALE-TOAD PREGNANCY TEST

lli Mainini's[1] account of the use of male s for the rapid diagnosis of pregnancy has wed by encouraging reports from workers parts of the world, including Wiltberger and the U.S.A., using *Rana pipiens*; Hinglais lais[3] in France, using *R. esculenta*; and n Britain, using *Bufo arenarum* Hensel (the nerican toad employed by Galli Mainini); nd Genover,[5] in Barcelona, using *B. calamita*, is, and *R. pipiens*; Bach and others,[6] in using *R. esculenta*; and Klopper and Frank,[7] d, using *B. vulgaris*.

per and Frank's series of 51 cases, the male- in 3 women who proved to be pregnant was whereas the Aschheim-Zondek test was

ritius none of the toads or frogs employed workers is to be found. The local toad, *B.* differs from *B. arenarum* Hensel in being ller; when fully grown it weighs only 20–25 In this toad the nuptial excrescences charac- the male in certain species[8] are incon- but Mr. R. Mamet, assistant entomologist partment of agriculture, pointed out to us that can be readily distinguished by a dark patch ted skin over the vocal sac. On dissecting we have found this sign infallible.

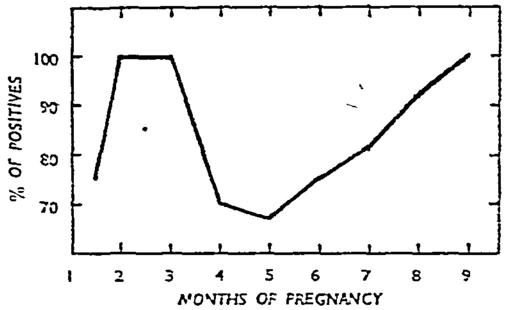
ber of male toads was kept in the laboratory n boxes with a supply of water in shallow ach was fed on 0·5 g. of beef thrice weekly, nended by Crew[9] for female xenopus. A positive invariably free of spermatozoa forty-eight er inoculation with pregnant urine; so we same toad several times with a resting period a week between tests.

ue.—Throughout the experiment Crew's technique jection of urine into the lymph-sac was followed. simple and permits of the release of the animal injection without risk of the urine oozing out he puncture. Before injection the toad's cloacal examined for spermatozoa, which were invariably

, for each test three toads were each injected with urine[4] without regard to their weight. The results were poor; only 40% were positive, and several toads died of toxæmia within an hour of injection. We therefore reduced the amount of urine injected to 5 ml., which proved to be still too much, only 70% giving positive results. Finally we injected 2·5 ml., 2 ml., and 1·5 ml. respectively into each of three toads and found these to be the most satisfactory quantities. With highly toxic samples the 1·5 ml. injection gave the best result, while with very dilute urines 2·5 ml. was best.

Results.—In all, 130 samples of urines were tested. The cases in which the test was made included 10 of amenorrhœa of 2–5 months' duration which later proved not to be due to pregnancy, 1 of hydatidiform mole of long standing, 1 of ectopic gestation which had ruptured eleven days previously, and 1 of a patient in the puerperium. In each of these 13 cases the result was negative.

Results from the remaining 117 samples are shown in the accompanying figure. The urines were of women in different stages of gestation. These results conform with the fact that excretion of gonadotrophic hormones in the urine of pregnant women increases from the first month to the third month, then gradually decreases to about the sixth month, and finally rises again till term.[10] The results also show that male *B. regularis* will nearly always respond to the injection of urine containing more than 5 units gonadotrophin. The marked sensitivity of the male toads to gonadotrophic hormones was reflected in the detection of pregnancy as early as the 5th day after the first missed menstrual period.



Many of the urines were not first morning specimens and some were twenty-four hours old on reaching the laboratory. By keeping the urines in a refrigerator the hormones could be preserved for several months and then still cause spermatogenesis in the toad; but urines not kept on ice might lose potency within forty-eight hours.

Our results agree with those obtained by other workers and show that the male toad *B. regularis* is as sensitive as the other species which have been used for pregnancy tests; it has moreover the advantage of needing a much smaller amount of urine (1·5 ml.) for the test.

We wish to thank Dr. A. Rankine, Director of Medical Services, Mauritius, for permission to publish these findings; Dr. H. D. Tonking, senior pathologist, for his keen interest and advice during the course of the experiment; and Dr. W. Dupré for his encouragement during this work.

Medical Department,
Mauritius.

A. Ng Cheung Hin
J. L. Webb.

Sir,—In your leading article of July 23 on hormone assays, you cited nine species of anura which had been found suitable for the male-toad test for urinary gonadotrophin. These frogs and toads were from America, Europe, and Asia. It may interest your readers in Africa to know that *Bufo regularis* appears to be equally suitable as a test animal. (I am indebted to Mr. G. S. Cansdale, superintendent of the London Zoo, for the identification.)

[10] Wright, S. Applied Physiology. London, 1947.

Since February, 1949, 125 male-toad pregnancy tests have been done with this toad in Accra, in cases of doubtful or suspected early pregnancy. Follow-ups have been very difficult to obtain, since African women often will not make a second visit to hospital, whilst European women who believe themselves to be pregnant commonly return to Europe.

Confirmation was obtained in 43 cases. Of 24 women whose urines gave a positive result, 23 were later found to be pregnant, and one had a hydatidiform mole. Of 19 women whose urines gave a negative result, 17 were found not to be pregnant and 2 to be pregnant. A number of the women with amenorrhœa whose urines gave a negative reaction cherished a faint hope that they might be pregnant; many such women did not return for the result of the test.

Bufo regularis weighs 30–50 grammes, and the male can be recognised by the pigmented patch on the radial aspect of the thumb.

The test was performed by injecting 5 ml. of fresh unprepared urine into the toad's dorsal lymph-sac; three hours later the toad's urine was examined for spermatozoa. Toads that had been in captivity for more than one week were more liable to die after the injection than fresh animals, and the urines of certain women were more toxic than others. In cases of lethal reaction the test was repeated with a fresh sample the following day; if still lethal the test was repeated with smaller doses.

In the case of hydatidiform mole a positive reaction was obtained with 0·05 ml. of urine; three days after evacuation of the patient's uterus the test was positive with 0·5 ml., and twelve days later the test was negative.

Placental separation results in the rapid disappearance of gonadotrophin from the urine. An African inpatient with suspected ectopic pregnancy gave a positive test; three days later she had sudden acute abdominal pain, and urine passed soon afterwards proved negative; meanwhile operation had revealed a ruptured tubal pregnancy of twelve weeks' maturity.

The results obtained suggest that positive reactions with this, as with toads used by other workers, are very reliable. Negative tests should be repeated if there is any clinical doubt.

The male-toad test is within the competence of any general medical practitioner. In West Africa *B. regularis* abounds in every garden, and the test should prove useful to those who are out of range of full laboratory facilities.

I am grateful to those colleagues who have completed follow-up forms on their cases, and to the Director of Medical Services, Gold Coast, for permission to publish this note.

Medical Research Institute,
Accra, Gold Coast.

MARK H. HUGHES.

MEMORIAL TO C. J. BOND

SIR,—It has been decided in Leicester to raise a fund for a memorial to the late Charles John Bond, C.M.G., F.R.C.S., and there may be friends of his elsewhere who would like to know about this project and be given an opportunity of showing their appreciation.

Bond was born in Leicestershire in 1856, and after his training at University College Hospital, London, he returned to live and work in Leicester until his death in 1939. He was pre-eminently a scientist, and his publications, which are very many and of great interest, show his surgery to have been far ahead of his time. His work was done in the Leicester Royal Infirmary but also, as was the custom in those days, often in the patient's home in the country under very simple conditions. In an exceedingly busy life he never ceased from original and experimental research. This he did in a wide range of subjects which brought him international recognition. He began with two papers on anatomy as a student, passing in turn to surgery, gynæcology, hæmatology, and genetics. Breeding experiments in birds and plants were carried out in his own garden. For forty years he was the close friend of the late Sir Victor Horsley, F.R.S., and
Bond showed in his book, *Recollections of Student
Later Years,* how closely their work was integrated.
During the 1914–18 war he was gazetted h
in the Army Medical Services and became con

was right."

Notes and News

THE YOUNG OFFENDER: A CONFERENCE

THE words "juvenile delinquency" are beginning to have an almost hackneyed ring in some ears: not unreasonably, perhaps, since the public interest excited by this topic is, in the words of the National Association for Mental Health, "quite out of proportion to the relatively small increase in juvenile crime." Opinions on treatment—usually by repressive and retributive measures—are much commoner than studies of causes or of the results of such measures. The association have examined 500 British press-cuttings collected during the first six months of this year, in order to learn what the public pick up from the newspapers about juvenile delinquency. Nearly three-quarters of the cuttings were of signed articles or letters, and many put environmental conditions—broken homes, and lack of living space, food, income, or parental affection or responsibility—among the leading causes; but commonly they ended by demanding greater discipline, punishment, and intimidation. Less than 15% mentioned prevention in any form. Facts, figures, or scientific method were rarely the background of the opinions given: "for many the prototype was clearly the contributor himself in his own childhood; for others the contributor's children, the schoolmaster's class of boys drawn from a particular district, the psychiatrist's or probation officer's highly selected problem cases."

It is possible—indeed likely—as the association note, that views collected in this way do not represent a true cross-section of public opinion, for some of them come from publicity-seekers or from those with special prejudices, while all are subject to editorial selection. Nevertheless the association fear that public interest in the subject—whatever its springs—is so strong that some action might be taken prematurely, before enough is known about the facts. They have therefore convened a conference, jointly with the British Psychological Society, the Howard League for Penal Reform, the Institute for the Scientific Treatment of Delinquency, the Institute of Sociology, and the Royal Medico-Psychological Association, to discuss "The Scientific Study of Juvenile Delinquency." The conference will be held on Saturday, Oct. 1, at the Royal Institution, 21, Albemarle Street, London, W.1, and details of the programme may be had from the secretary, National Association for Mental Health, 39, Queen Anne Street, London, W.1. Invited delegates will represent the Church, judiciary bodies, statutory officials, Government departments, social workers, youth organisations, voluntary bodies, universities, and other educational authorities, as well as the medical and legal professions. A critical examination of delinquency by informed people can do nothing but good, and the conference deserves to be well attended.

FILMS ON THIOPENTONE AND SULPHONAMIDES

Messrs. May & Baker Ltd. have copies of the following medical films which they will lend on request: (1) *Thiopentone Sodium and its Use in Intravenous Anæsthesia*, made in coöperation with the Department of Anæsthetics, Westminster Hospital, London; running-time 38 minutes, on 16 mm. and 35 mm. sound. (2) *Medical Applications of Sulphonamides*; running-time 34 minutes, on 16 mm. and 35 mm. sound. Both films are divided into three sections—introduction (chemistry), pharmacology, and clinical use. Applications, specifying alternative dates when possible, should be addressed to Documentary Film Unit, May & Baker Ltd., Dagenham, Essex, from whom synopses may also be obtained.

Royal College of Obstetricians and Gynæcologists

On Wednesday, Oct. 12, at 2.30 P.M., Prof. R. W. Johnstone will deliver the William Meredith Fletcher Shaw lecture. His subject is to be Scotland's Contribution to the Progress of Midwifery in the 18th and early 19th Centuries.

Regional Board's Revised Estimate Approved

The Minister of Health is reported by the *Daily Telegraph* (Sept. 12) as having approved Sheffield regional hospital board's revised estimate of £12,900,000 for maintenance expenditure in the current year. The board's original estimate of £10,624,580 had been reduced by £221,000; and the new estimate was drawn up in response to the Minister's request. This request was addressed to all boards; and the Sheffield estimate is the first of the revised estimates to be sanctioned.

---

[1] See *Lancet*, 1947, i, 72.

Since February, 1949, 125 male-toad pregnancy tests have been done with this toad in Accra, in cases of doubtful or suspected early pregnancy. Follow-ups have been very difficult to obtain, since African women often will not make a second visit to hospital, whilst European women who believe themselves to be pregnant commonly return to Europe.

Confirmation was obtained in 43 cases. Of 24 women whose urines gave a positive result, 23 were later found to be pregnant, and one had a hydatidiform mole. Of 19 women whose urines gave a negative result, 17 were found not to be pregnant and 2 to be pregnant. A number of the women with amenorrhœa whose urines gave a negative reaction cherished a faint hope that they might be pregnant; many such women did not return for the result of the test.

Bufo regularis weighs 30–50 grammes, and the male can be recognised by the pigmented patch on the radial aspect of the thumb.

The test was performed by injecting 5 ml. of fresh unprepared urine into the toad's dorsal lymph-sac; three hours later the toad's urine was examined for spermatozoa. Toads that had been in captivity for more than one week were more liable to die after the injection than fresh animals, and the urines of certain women were more toxic than others. In cases of lethal reaction the test was repeated with a fresh sample the following day; if still lethal the test was repeated with smaller doses.

In the case of hydatidiform mole a positive reaction was obtained with 0·05 ml. of urine; three days after evacuation of the patient's uterus the test was positive with 0·5 ml., and twelve days later the test was negative.

Placental separation results in the rapid disappearance of gonadotrophin from the urine. An African inpatient with suspected ectopic pregnancy gave a positive test; three days later she had sudden acute abdominal pain, and urine passed soon afterwards proved negative; meanwhile operation had revealed a ruptured tubal pregnancy of twelve weeks' maturity.

The results obtained suggest that positive reactions with this, as with toads used by other workers, are very reliable. Negative tests should be repeated if there is any clinical doubt.

The male-toad test is within the competence of any general medical practitioner. In West Africa *B. regularis* abounds in every garden, and the test should prove useful to those who are out of range of full laboratory facilities.

I am grateful to those colleagues who have completed follow-up forms on their cases, and to the Director of Medical Services, Gold Coast, for permission to publish this note.

Medical Research Institute,
Accra, Gold Coast.

MARK H. HUGHES.

MEMORIAL TO C. J. BOND

SIR,—It has been decided in Leicester to raise a fund for a memorial to the late Charles John Bond, C.M.G., F.R.C.S., and there may be friends of his elsewhere who would like to know about this project and be given an opportunity of showing their appreciation.

Bond was born in Leicestershire in 1856, and after his training at University College Hospital, London, he returned to live and work in Leicester until his death in 1939. He was pre-eminently a scientist, and his publications, which are very many and of great interest, show his surgery to have been far ahead of his time. His work was done in the Leicester Royal Infirmary but also, as was the custom in those days, often in the patient's home in the country under very simple conditions. In an exceedingly busy life he never ceased from original and experimental research. This he did in a wide range of subjects which brought him international recognition. He began with two papers on anatomy as a student, passing in turn to surgery, gynæcology, hæmatology, and genetics. Breeding experiments in birds and plants were carried out in his own garden. For forty years he was the close friend of the late Sir Victor Horsley, F.R.S., and Bond showed in his book, *Recollections of Studen Later Years*, how closely their work was integrat

During the 1914–18 war he was gazetted h in the Army Medical Services and became cons (with the late Lord Moynihan) to the Northern He was a member of the Medical Research Council represented on the Inter-Allied Commission on War Wounds, which met in Paris in 1916–18. years he studied wounds, immunity, the effect of on body tissues, and leucocyte activity, finding publish his own observations which are of particula in relation to the work on these subjects in the war twenty-five years later.

Throughout his work, in all its ramifications, he his wide experience and philosophy with the problems of the times. Were he alive today undoubtedly have been keenly interested in the which he foresaw as early as 1912. Nothing was daunt him nor too trivial to be ignored. He recorded, and deduced with courage, but there was teristic humility and consideration for the opinions

Surely it must be unique for a surgeon unatt of the great teaching hospitals to have carried out valuable work on so many subjects, based on a logical foundation. Bond decided to work in the at a place where, though the material is always a good, there is no medical school and for many of years of his life there was no laboratory ac It seems fitting that such a life should be comm our inspiration.

It is proposed to place a plaque in the Leicester Infirmary, and also to create a fund to enable in biology at the Leicester University College greater opportunities for research and trav contribution to this memorial should be sent to treasurer, Dr. L. K. Harrison, 2, Springfield Leicester.

JOAN B. W
N. I. Sp
Joint Hon.

Leicester.

Medicine and the Law

The Wrong Blood

LAST week the assistant deputy West London returned a verdict of death by *misadvent* case of a 43-year-old man who died after t with incompatible blood. According to the *Guardian* (Sept. 9), a laboratory technician at t where the transfusion was given stated in evid during her absence, an unlabelled specimen w from a nurse by another technician, and "the the technician that it was the man's blo coroner concluded that there had been a mistake course of the transmission of the blood from the the pathological department, or possibly in the logical department itself, by which presumably t blood was matched and the wrong blood tr "I am satisfied," he concluded, "that there i that blood specimens must be labelled before t accepted and I am satisfied that the rule is enforced; but all hospital rules of this sort liable to a certain amount of elasticity and t undoubtedly a case of emergency."

Wrong Cylinder Once Again

Yet another fatal accident through an error in of anæsthetic cylinders was disclosed in the pr in Dublin on Sept. 4 of a woman doctor on a c illegal killing of a patient.

The patient entered hospital for a minor ope which an anæsthetic was required. The mac for administering the anæsthetic contained two c one for nitrous oxide and one for oxygen. The finding the oxygen cylinder empty, asked a replace it; the nurse took a cylinder from

TO THE ÆTIOLOGY OF GRAVES'S DISEASE *

J. H. MEANS
M.D. Harvard
PROFESSOR OF CLINICAL MEDICINE, HARVARD
RSITY; CHIEF OF THE MEDICAL SERVICES,
SSACHUSETTS GENERAL HOSPITAL, BOSTON

hyperthyroidism is usually present at some raves's disease this is not to be regarded as y simple endocrinopathy like primary athy- ull's disease; it is a widespread and complex mal disorder involving, besides the thyroid, ocrine glands, the tissues of the orbit, the he thymus, and the lymphatic, reticulo- l, hæmopoietic, muscular, nervous, and very r bodily systems.

iology of Graves's disease is a challenging r inquiry, and, particularly as regards its nifestations, its treatment presents an urgent or the clinician. I cannot offer any solutions; rely make surmises and indicate approaches eing used and clues which it may be profitable in the future.

's disease the primacy of the thyroid gland, y use that term in a negative sense, is indis- The gland has undergone atrophy or been , and all the manifestations of the disease may reted as the result, direct or indirect, of lack d hormone throughout the body. One cannot al confidence assert that Graves's disease ally the opposite. The primacy of the thyroid Graves's disease has never been conclusively ed.

wish to see simple hyperthyroidism we can feed land to normal people, or we can find it occurring in cases of oversecreting thyroid adenoma. ckground to our inquiry into the nature of disease, it may be well to examine this seemingly isturbance.

TOXIC ADENOMA OF THE THYROID

te Henry S. Plummer (1926), of the Mayo as chiefly responsible for distinguishing between enoma of the thyroid and Graves's disease, or lmic goitre, as he preferred to call it, and for g them as of different origin. For many years d the validity of this distinction. I never denied ence of toxic adenoma; indeed I admitted that, ere were plenty of instances of oversecreting in other endocrine glands, it was reasonable t them in the thyroid. However, I failed to , in my clinic, cases which on clinical grounds confidently call Plummer's disease rather than disease. The thyrotoxic patients with nodules thyroid glands I took to be cases of Graves's with goitres which happened to be nodular.

dvent of radioactive iodine has entirely changed rpretation. We have proved with this agent e oversecreting tumours may occur in the thyroid, t the hyperthyroidism they produce is ætio- distinct from that of Graves's disease. The alone oversecretes in Plummer's disease; the land in Graves's disease.

highly probable that the activities of all tissues, true neoplasms, are under either nervous or l control, or both. Neoplasms are almost cer- ot under nervous control, and it seems likely ey have also largely escaped from humoral

Investigation of Function

The function of thyroid adenomata can be studied by giving the patient tracer doses of radioactive iodine. It is well established now by extensive investigations on animals that the uptake of labelled iodine by the thyroid gland is a dependable index of the rate of secretory activity of the thyroid cells. Uptake after administration of tracer doses can be determined in at least three ways: scanning over the region of the thyroid with an externally applied Geiger counter is the most direct way; excision of thyroid tissue and the making of autoradiograms with tissue slices is another; and a third, indirect, method is to determine what proportion of the administered dose of radioactivity is excreted in the urine, and then to assume that the remainder has been retained for the most part by the thyroid gland.

When one applies these methods to the study of thyroid tumours, the results range from that in which a tumour takes up no iodine, and hence is to be regarded as totally inactive, to one in which a tumour takes up iodine with great avidity and the remainder of the thyroid takes up little or none.

Malignancy

In the thyroid gland, as in most other tissues, both benign and malignant tumours may be found. Whether the malignant tumours only originate in the benign or may arise de novo from previously normal tissue is unknown. There is plenty of evidence that benign thyroid tumours may ultimately become malignant. But it is also apparent that malignant tumours usually secrete only slightly, if at all, whereas benign ones may secrete enough to produce hyperthyroidism, and when they have done so the possibility of their becoming also malignant is remote. Indeed, it is extremely rare to find cancer in the thyroid gland of any thyrotoxic persons, whether the source of their hyperthyroidism is a tumour or the diffuse hyperplasia of Graves's disease. For many years we considered hyperthyroidism a good guarantee against thyroid cancer. Recently we have found histologically malignant nodules buried in the hyperplastic thyroids in five cases of Graves's disease; none of them formed metastases, and what might have happened to them had they remained in situ cannot be said. In spite of this experience we still believe that, to a large extent, hyperplasia and malignant neoplasia are mutually exclusive. The significance of this relationship is not yet apparent, but it may later become so. It is worth bearing in mind.

Life History of Adenoma

The life history of the oversecreting thyroid nodule has been well worked out in our clinic with radioactive iodine by Dobyns and Lennon (1948). The important phases are shown diagrammatically in fig. 1. Here is portrayed an adenoma which produces thyroid hormone from its birth onwards. In the beginning it is very small and its contribution of hormone is insignificant compared with that of the rest of the gland. The thyroid gland, as the diagram shows, is under pituitary control, making just enough total hormone to maintain the patient in a euthyroid state. However, the tumour grows out of control and, as it does so, contributes more and more hormone in simple relation to the total volume of its parenchyma. The pituitary gland, we suspect (it has not been proved), in these circumstances restricts its output of thyroid-stimulating hormone so that as the tumour produces more and more hormone, the remainder of the thyroid, in compensation, makes less and less. Finally, as the tumour grows, the time comes when it alone makes enough thyroid hormone to keep the patient in a euthyroid state. At this point, we suspect, on the basis of what is actually known of pituitary-thyroid

lecture delivered at University College Hospital Medical ol, London, on June 23, 1949.

Edinburgh Post-Graduate Board for Medicine

On Tuesday, Sept. 20, Prof. S. L. Baker will speak on Bone and Joint Pathology, and on Thursday, Sept. 22, Prof. C. H. Browning, F.R.S., on Bacteriological Principles Governing Chemotherapy. Both lectures will be given at 4.30 P.M. in the anatomy lecture theatre of Edinburgh University.

International Congress of Forensic and Social Medicine

The third congress of the International Academy of Forensic and Social Medicine will be held in Cairo from March 21 to 26, 1950.

Welsh National School of Medicine, Cardiff

The opening sessional address of this school will be given on Thursday, Oct. 6, by Dr. William Pickles, medical officer of health for Aysgarth.

Biochemical Society

A meeting of this society will be held in the department of biochemistry, School of Medicine, Leeds, 2, on Friday, Sept. 23, at 11 A.M.

Royal Free Hospital School of Medicine

At 3 P.M. on Friday, Sept. 30, at B.M.A. House, Tavistock Square, London, W.C.1, Mr. James Laver will deliver the inaugural address of the new session. His subject will be Clothes and Psychic Health.

Oliver Memorial Fund

The second award of this Fund has been made to Dr. H. F. Brewer, clinical pathologist to St. Bartholomew's Hospital. Dr. Brewer has been medical officer to the British Red Cross London Blood Transfusion Service for 16 years.

Minister of Health to Visit India

Mr. Aneurin Bevan has accepted an invitation from Mr. Nehru to visit India. A Reuter message, quoted by the *Times* (Sept. 12), says that the invitation is understood to have been prompted by Mr. Nehru's desire to have Mr. Bevan's advice on India's health problems.

Review of Cancer Research

A series of fifteen articles on cancer has been prepared by Mr. Lester Grant, of the *New York Herald Tribune*, with the help of the U.S. Public Health Service and the American Cancer Society. The articles, which review progress in this field, in language understandable to the layman, may be obtained without charge on application to the department of natural sciences, UNESCO, 19, Avenue Kléber, Paris 16°.

Rheumatism Centre for Sheffield

Sheffield is to have a centre for the investigation and treatment of rheumatic disorders. The *Sheffield Telegraph* (Sept. 6) reports that this is to be set up jointly by the board of governors of the United Sheffield Hospitals and the regional hospital board; research will be developed by the two boards in collaboration with the university. A full-time consultant is to take charge of the centre.

Course on Rehabilitation of the Disabled

Twenty European delegates—physicians, surgeons, and specialists in social affairs—are to attend a course next month on the rehabilitation and resettlement of the disabled. The course, which will be under the general direction of Dr. Harold Balme, of the Ministry of Health, and Mr. G. C. H. Slater, of the Ministry of Labour and National Service, has been arranged by the British Council, in coöperation with these two Ministries and the Ministry of Pensions. A similar course was held last year.

U.S. Congress Delegation in Britain

Members of the House of Representatives' committee concerned with the national health insurance legislation introduced by the Administration in Congress, have been in England this week. On Monday they visited the Ministry of Health where they talked with the Minister and officials; and the programme arranged for them between then and their departure for Stockholm on Friday included a day in Oxford and visits to King's College Hospital, Guy's Hospital, and the headquarters of the North-West Metropolitan regional hospital board, London County Council, and the Nuffield Foundation. Meetings were also arranged with representatives of the Medical Practices Committee and the Dental Estimates Board, and with Dr. Charles Hill, secretary of the British Medical Association.

C.M.F. Surgeons' Club

The annual dinner of this club will take place
Hotel, London, W.1, on Sept. 29. Applications and cheques for 25*s*. should be sent to Mr. Guy
Keats House, Guy's Hospital, S.E.1.

Chadwick Lectures

On Thursday, Dec. 8, at 4.30 P.M., at St. Mary,
medical school, Praed Street, London, W.2, Dr G
will give the Malcolm Morris lecture on Generalised Sclerosis. Details of other public lectures to be
autumn may be had from the secretary of the
Abbey House, Westminster, S.W.1.

'Paramisal Sodium,' manufactured by Her
ceuticals Ltd., will in future be marketed in the name 'Paramisan Sodium,' which has hitherto
only abroad.

The effect on National Insurance benefits of
hospital is explained in a leaflet (N.I.9), of which
to keep a stock for the use of patients.

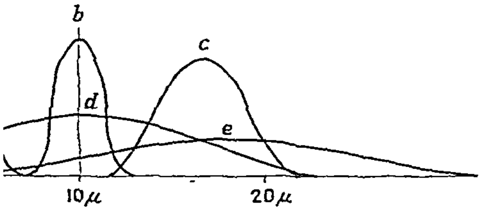
of scanning neck with directional Geiger counter: numerals indicate counts per minute over areas indicated. (After Dobyns.)

t in Graves's disease it may be 10–20 times e number of counts partly depends on the thyroid tissue just beneath the counter. interpreting results one must give some atomy.

and diagram shows what one might find al thyroid gland, and the diagram next t of result found with the diffusely hyper- : in Graves's disease. The third diagram hyroid gland in Graves's disease with an dule. The nodule here, the masses of tissue



cy curves of thyroid cell heights in (a) normals, (b) ase, (c) oversecreting adenoma ("hot" nodule), (d) ng adenoma ("cold" nodule), and (e) adenocarcinoma. s.)

ng taken into consideration, does not take ntly greater amount of iodine than does the parenchyma. It is a relatively cold nodule, not more than a lukewarm one. The fourth grams show typical examples of hot and cold therwise normal thyroids. The hot nodule, ted at an upper pole where counts tend be low, gives a significantly higher value than aining parenchyma, whereas the cold nodule, rge mass of tissue, gives a lower value than cept the right upper pole, where a low value pected.

nd Skanse (1949) have used the ratio of ction by nodules to collection by extra- roid tissue to distinguish between secreting creting lesions. Any value for this ratio hey regard as denoting an oversecreting

odine Collection to Parenchymal Cell Height

of interest both in non-neoplastic and in issue. As I mentioned earlier, we had con- the work of Rawson and Starr (1938), that s a good index of thyroid activity. Increase ht denoted cellular hypertrophy, and hyper- an accompaniment of oversecretion. This is probably justified so far as non-neoplastic oncerned, but Dobyns and Skanse (1949) red the heights of the epithelial cells of thyroid d find some departures from the rule governing stic tissue. In brief, they find in some tumours are high but inactive. In an effort to solve they studied *not only mean cell height but* ution curves of cell height. The gist of their moothed a bit, is shown in fig. 4. Here we ency curves of thyroid acinar cell height- those of Price Jones on erythrocyte diameter: (*a*) in normal thyroids, (*b*) in Graves's disease, (*c*) in an oversecreting thyroid adenoma (hot nodule), (*d*) in an undersecreting or non-secreting adenoma, and (*e*) in an adenocarcinoma of the thyroid.

It appears from these curves that relative uniformity in cell height is characteristic of normal and of non-neoplastic hyperplastic tissue. Increasing variability in cell height marks the transition from normal or simple hyperplastic tissue to neoplastic tissue, and the cells of secreting neoplastic tissue vary less in height than those of non-secreting neoplastic tissue.

GRAVES'S DISEASE

Ophthalmopathy

One of the most amazing manifestations of Graves's disease is the ophthalmopathy; what on earth can it have to do with the thyroid? There are syndromes due to oversecretion by other non-neoplastic endocrine glands—adrenal cortex, parathyroid, gonad, &c.—but none of these, so far as I know, includes anything as bizarre or apparently unrelated to the function of the primarily involved endocrine gland as is the ophthalmopathy of Graves's disease. I always react vigorously when *the eye signs are enumerated among the signs* of thyrotoxicosis. They are not signs of thyrotoxicosis, because they may progress when the patient is in a *hypothyroid* phase. I think the most reasonable position to take is that ophthalmopathy and thyrotoxicosis are both manifestations of Graves's disease, but that one is in no sense the result of the other. Either may be lacking at some stage of the disease in any given case.

Since exophthalmos was first produced by injections of anterior-pituitary extracts, it has generally been believed that an excessive production of thyrotropic hormone plays some important rôle in its pathogenesis. But, if this is true, how is it that ophthalmopathy and thyrotoxicosis in Graves's disease can vary independently, or at least in non-parallel fashion? This dilemma brings *to mind the question of end-organ sensitivity*, and perhaps also of chalones which might antagonise the action of thyrotropic hormone. The only proved end-organ of thyrotropic hormone, so far as I know, is the thyroid parenchyma. If the tissues of the orbit are also specific end-organs for this hormone, it seems a remarkable relationship. The growth hormone, and perhaps the diabetogenic hormone, act on non-endocrine targets, but otherwise the tropic hormones of the pituitary gland act, seemingly, only on other endocrine glands.

The work of Rawson and Starr (1938) on thyrotropic hormone indicates that its first action on the thyroid gland is to accelerate the release of thyroid *hormone*. In serving this function it becomes physiologically inactivated, but by treatment with mild reducing agents its activity can be restored. As regards the inactivation of thyrotropic hormone, Rawson and Starr also made two other discoveries which may be of deep *significance*: (1) the thyroid glands of patients with Graves's disease can inactivate more thyrotropic hormone than can those of normal people; and (2) besides the thyroid gland, lymph-node tissue and thymus gland can likewise inactivate thyrotropic hormone.

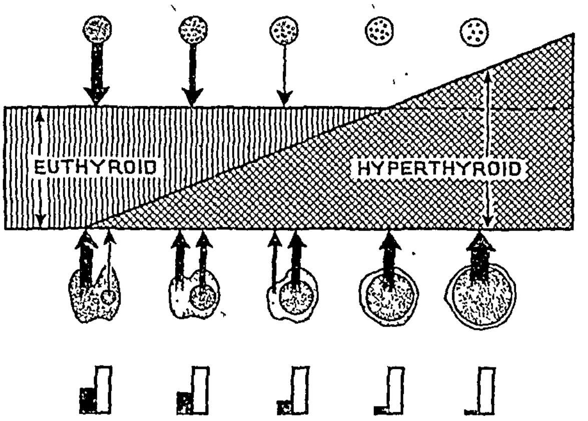


Fig. 1—Life history of secreting thyroid adenoma ("hot" nodule). Upper row of circles represents anterior lobe of pituitary gland; intensity of stippling and width of arrows indicate degree of thyrotropic activity.

Lower row of circles, enlarging from left to right, denote growth of tumour in thyroid gland; intensity of stippling denotes functional activity disclosed by uptake of radioactive iodine. Arrows, by their thickness, indicate contribution of thyroid hormone by both tumour and remainder of thyroid gland.

Single-hatched zone indicates portion of B.M.R. produced by hormone from non-neoplastic thyroid parenchyma, and cross-hatched zone that by hormone from tumour.

Columns at base represent cell height: black, of thyroid parenchyma; white, of tumour.

balance, that the pituitary gland ceases altogether to produce thyroid-stimulating hormone, and the normal thyroid parenchyma consequently becomes atrophic and functionless. However, the process does not stop here. The tumour, being out of control, continues to grow *and make even greater quantities of thyroid hormone.* The patient therefore at last becomes thyrotoxic and enters a stage in which he can be truly said to have a toxic adenoma of the thyroid.

This diagrammatic simplification (fig. 1) is based not only on collections of radio-iodine by the thyroid and basal metabolic rates (B.M.R.) but also on measurements of the mean acinar cell height of the thyroid parenchyma. The extensive studies of Rawson and Starr (1938) have demonstrated a close relation between the height of thyroid cells and their functional activity. Dobyns and Lennon (1948) have shown that the same holds true, usually but not always, for the epithelium of thyroid tumours. In fig. 1 I have therefore indicated *cell heights as well as function estimated from iodine* collections. The height of the tumour cells, it will be seen, is above that of the normal cells from the beginning and remains fixed at this high level, whereas that of the normal cells steadily declines as the tumour takes over and the *pituitary gland restricts its output* of thyrotropic hormone.

The situation in Graves's disease is altogether different. Here we have no evidence that the thyroid parenchyma escapes from hormonic control. Unless, perchance, the sensitivity of thyroid cells as end-organs is altered, which is possible but not proved, we may assume that the thyroid abnormality in Graves's disease lies in the control of the thyroid gland rather than in the gland itself.

Pituitary-thyroid Axis

Salter (1940) referred to the pituitary-thyroid relationship as the pituitary-thyroid axis, and this is a convenient term to use. The pituitary gland makes a hormone which stimulates the thyroid gland to make its hormone, which in turn inhibits the pituitary gland. It may be regarded as, within limits, an automatic physiological mechanism. As I conceive the situation in toxic adenoma of the thyroid, it is one in which the axis functions ably to preserve the euthyroid state of the patient until the limit of its ability to effect an adjustment is reached. *Only at this point does the patient* thyrotoxic. In the thyrotoxicosis of Graves's on the other hand, I regard the axis as out of from the beginning or as receiving a morbid from the hypothalamus.

In fig. 2 I have indicated these relationships. we have parallel increases in iodine uptake, size, cell height, and B.M.R. All these may be due increased thyrotropic activity of the pituitary or possibly to increased sensitivity of the thyroid to its pituitary stimulator. If the latter were the one would expect compensation for a time until it its limit. Whether such compensation occurs determining. An approach seems to be to dis *what really is the normal stimulus to the th* function of the pituitary gland. Is it the absolute of thyroid hormone in the blood, the B.M.R. of patient, or what? The answer to this question provide a clue to the ætiology of Graves's disease.

Results Obtained with Radio-iodine

In fig. 2 I have also indicated one of the reasons for scepticism, before the days of radio-iodine, about existence of toxic thyroid adenoma. Graves's may occur in persons with non-secreting nodules their thyroids; this condition would be called, descriptively, toxic nodular goitre, but it is Graves's disease with incidental thyroid nodule nodules, neoplastic or other. Before radio-iodine ca along, such situations made for confusion; now its use we can very easily separate secreting from no secreting nodules and thus understand the process more accurately. In our clinic we call se *nodules "hot" and non-secreting nodules* "cold and for convenience I shall use that terminology fr here on.

The sort of thing one finds on scanning the neck wi the directional Geiger counter after a tracer dose of radi iodine, in the several conditions I have been talki about, is shown in fig. 3. The circles indicate the locati of the aperture of the counter, and the numerals indica the detected nuclear disintegrations per minute observe in those areas. The normal value is 200–400 count

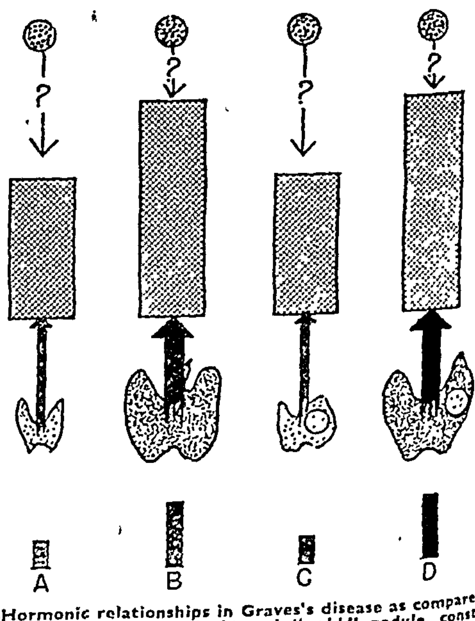

Fig. 2—Hormonic relationships in Graves's disease as compared with normal, with or without incidental "cold" nodule, constructed in similar fashion as fig. 1. Height of cross-hatched rectangles indicates B.M.R.; columns at base denote height of thyroid acinar cells. A, normal thyroid; B, Graves's disease with thyrotoxicosis; C, normal thyroid with incidental nodule; D, Graves's disease with incidental nodule.

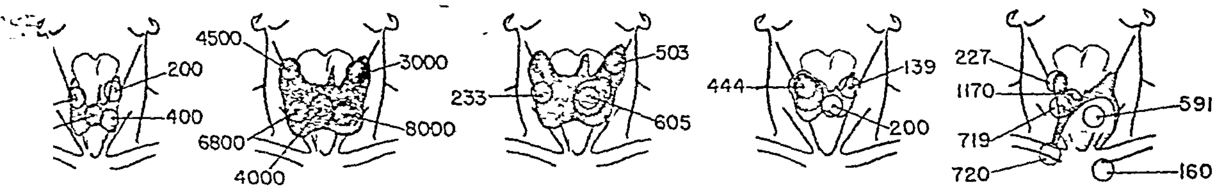
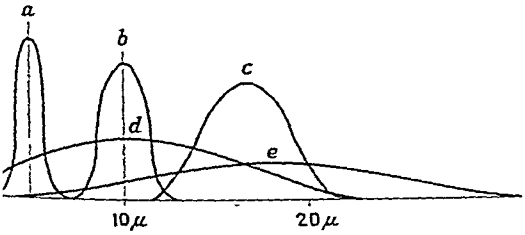


esults of scanning neck with directional Geiger counter: numerals indicate counts per minute over areas indicated. (After Dobyns.)

te, but in Graves's disease it may be 10–20 times . The number of counts partly depends on the ss of thyroid tissue just beneath the counter. re in interpreting results one must give some to anatomy.

left-hand diagram shows what one might find normal thyroid gland, and the diagram next ie sort of result found with the diffusely hyper- gland in Graves's disease. The third diagram the thyroid gland in Graves's disease with an tal nodule. The nodule here, the masses of tissue d being taken into consideration, does not take nificantly greater amount of iodine than does the the parenchyma. It is a relatively cold nodule, inly not more than a lukewarm one. The fourth h diagrams show typical examples of hot and cold in otherwise normal thyroids. The hot nodule. located at an upper pole where counts tend ly to be low, gives a significantly higher value than e remaining parenchyma, whereas the cold nodule, a large mass of tissue, gives a lower value than a except the right upper pole, where a low value be expected.



requency curves of thyroid cell heights in (a) normals, (b) 's disease, (c) oversecreting adenoma ("hot" nodule), (d) ecreting adenoma ("cold" nodule), and (e) adenocarcinoma. Dobyns.)

ns and Skanse (1949) have used the ratio of collection by nodules to collection by extra- r thyroid tissue to distinguish between secreting on-secreting lesions. Any value for this ratio 1 they regard as denoting an oversecreting .

n of Iodine Collection to Parenchymal Cell Height

is of interest both in non-neoplastic and in stic tissue. As I mentioned earlier, we had con- , on the work of Rawson and Starr (1938), that ight is a good index of thyroid activity. Increase height denoted cellular hypertrophy, and hyper- was an accompaniment of oversecretion. This sion is probably justified so far as non-neoplastic is concerned, but Dobyns and Skanse (1949) measured the heights of the epithelial cells of thyroid rs and find some departures from the rule governing oplastic tissue. In brief, they find in some tumours which are high but inactive. In an effort to solve iddle they studied not only mean cell height but istribution curves of cell height. The gist of their s, smoothed a bit, is shown in fig. 4. Here we frequency curves of thyroid acinar cell height r to those of Price Jones on erythrocyte diameter: (a) in normal thyroids, (b) in Graves's disease, (c) in an oversecreting thyroid adenoma (hot nodule), (d) in an undersecreting or non-secreting adenoma, and (e) in an adenocarcinoma of the thyroid.

It appears from these curves that relative uniformity in cell height is characteristic of normal and of non-neoplastic hyperplastic tissue. Increasing variability in cell height marks the transition from normal or simple hyperplastic tissue to neoplastic tissue, and the cells of secreting neoplastic tissue vary less in height than those of non-secreting neoplastic tissue.

GRAVES'S DISEASE

Ophthalmopathy

One of the most amazing manifestations of Graves's disease is the ophthalmopathy; what on earth can it have to do with the thyroid? There are syndromes due to oversecretion by other non-neoplastic endocrine glands—adrenal cortex, parathyroid, gonad, &c.—but none of these, so far as I know, includes anything as bizarre or apparently unrelated to the function of the primarily involved endocrine gland as is the ophthalmopathy of Graves's disease. I always react vigorously when the eye signs are enumerated among the signs of thyrotoxicosis. They are not signs of thyrotoxicosis, because they may progress when the patient is in a hypothyroid phase. I think the most reasonable position to take is that ophthalmopathy and thyrotoxicosis are both manifestations of Graves's disease, but that one is in no sense the result of the other. Either may be lacking at some stage of the disease in any given case.

Since exophthalmos was first produced by injections of anterior-pituitary extracts, it has generally been believed that an excessive production of thyrotropic hormone plays some important rôle in its pathogenesis. But, if this is true, how is it that ophthalmopathy and thyrotoxicosis in Graves's disease can vary independently, or at least in non-parallel fashion? This dilemma brings to mind the question of end-organ sensitivity, and perhaps also of chalones which might antagonise the action of thyrotropic hormone. The only proved end-organ of thyrotropic hormone, so far as I know, is the thyroid parenchyma. If the tissues of the orbit are also specific end-organs for this hormone, it seems a remarkable relationship. The growth hormone, and perhaps the diabetogenic hormone, act on non-endocrine targets, but otherwise the tropic hormones of the pituitary gland act, seemingly, only on other endocrine glands.

The work of Rawson and Starr (1938) on thyrotropic hormone indicates that its first action on the thyroid gland is to accelerate the release of thyroid hormone. In serving this function it becomes physiologically inactivated, but by treatment with mild reducing agents its activity can be restored. As regards the inactivation of thyrotropic hormone, Rawson and Starr also made two other discoveries which may be of deep significance: (1) the thyroid glands of patients with Graves's disease can inactivate more thyrotropic hormone than can those of normal people; and (2) besides the thyroid gland, lymph-node tissue and thymus gland can likewise inactivate thyrotropic hormone.

Warthin (1938) attached great importance to the involvement of lymphoid tissue in Graves's disease. He claimed that it constituted the most striking feature of the histopathology of the disease, and he looked on it as an expression of a constitutional state of the thymicolymphatic type which he called the "Graves's constitution." Unless one were born with this, so Warthin claimed, one would never get exophthalmic goitre. I am not prepared to accept Warthin's contentions unreservedly, but I am to some degree in sympathy with them. There can be small doubt that inheritance plays some rôle in Graves's disease; also it is impressive that lymphoid high lights keep appearing, first in one place and then in another, in the over-all picture.

When Rawson and Starr found that lymph-node tissue, as well as thyroid and thymus tissue, would inactivate thyrotropic hormone, I at once thought of Warthin's old theory. I also recalled that in the ophthalmopathy of Graves's disease the ocular muscles are invaded by lymphocytes—indeed actual lymphorrhages may be found in them. All these facts concerning lymphatic tissue in Graves's disease must be related and must have some significance, but what it may be I cannot tell. Perhaps, however, Warthin was right, and here may lie one clue, at least, to the enigma of Graves's disease. Certainly the lymphatic component deserves further and vigorous study, and so does the muscular component. It is well known that some patients present a myopathy not merely in the orbit but also throughout the entire skeletal muscular system. Instead of the orbits being selectively involved, it is possible that the state of affairs there is merely a local exaggeration of a widespread process, conditioned by local peculiarities.

In any event, in my own thinking, I keep returning to the orbit. I cannot escape a strong conviction that the solution to the problem it presents may solve that of the whole disease. The production of exophthalmos in animals with pituitary extracts seems a very important clue, but it is disconcerting (1) that none of the preparations of thyrotropic hormone thus far used are completely pure, which fact leaves open the possibility of their containing an exophthalmos-producing substance other than thyrotropic hormone; and (2) that so far as I can discover, Graves's disease does not occur in animals, which fact leaves open the possibility that the exophthalmos produced in them differs in pathogenesis from that of Graves's disease in man.

In human Graves's disease there are two categories of eye signs: (1) wide palpebral fissures, lid retraction, and lid lag, due to levator spasm; and (2) swelling of the orbital tissues, which pushes the eyeballs forward and exudes round the globes, causing swelling of the eyelids (Rundle and Pochin 1944). The characteristic limitation in the movement of the eyeballs is interpreted as a result of weakness of the extrinsic muscles, which are the seat of a myopathy, itself an essential part of the total Graves's syndrome. The morbid anatomy, in its gross features, is fairly well known. There is, as Rundle and Pochin clearly showed, an increase in the total fat in the orbit. There is also, at least in the severer stages, an increase in orbital water content. The muscles display, in the more malignant types, a profound and characteristic myopathy. They are invaded both by fat and by lymphoid elements. What we need now is some biochemical, especially cytochemical, information about this amazing lesion.

It has seemed to me for some years that quantitative data on intraorbital pressure and records of how it is affected by treatment might be particularly illuminating. I was therefore delighted to receive a monograph on clinical orbitonometry with the description of a successful orbitonometer from Dr. A. C. Copper (1948) of Leiden. I have since visited his laboratory. Copper's permits the measurement of the backward displac of the eyeball when any desired pressure is ap its anterior surface.† Such measurements, I am can be accepted as indices of intra-orbital pr Copper's orbitonometer is at the same time an ex exophthalmometer—i.e., it can be used to the exact position of the eyeball in relation to connecting the outer bony angles of the two One measures simultaneously the intra-orbital p and the degree of proptosis. The proptosis can be to be the resultant of the forces which tend to the cyball out—i.e., increased orbital pressure swelling—and the forces which tend to pull it —i.e., the tug exerted by the muscles. Whatev actual strength of these opposing forces, it mu assumed that, when the position of the eyeball, or otherwise, is stationary, these forces must equal.

Copper reports orbitonometric data on normal p and in Graves's disease and acromegaly. I quote his conclusions as follows:

> "In thyrotoxicosis and classic Graves's disease o tension was either normal or increased. An increase more evident in eight postoperative cases. The c most likely suggest a state of mild œdema of the o tissues.
>
> "In the hyperophthalmopathic type orbital tension markedly increased, like in diffuse infiltration. On the cases showed a progress to normal in the cour treatment with thyroid extract.
>
> "Both our clinical observations and the orbitonom results are in accord with Means's concept of a 'spec of types of phases within the clinical entity.' Orbit metry assists in differentiating the types and in diagn a possible progression to hyperophthalmopathy."

Copper here refers to my expressed belief that is no such thing as a type of malignant exophthal ætiologically distinct from Graves's disease. I glad to find that he agreed with me. I believe Po does also.

Copper's observation that in one case in the hyper thalmopathic phase the orbital pressure dropped normal during treatment with thyroid extract I particularly exciting, though one case proves noth We have given thyroid extract in cases of progres ophthalmopathy on the theory that it inhibits pituitary gland as regards oversecreting of what thyrotropic or other hormone causes the lesion. beneficial effect is neither prompt nor dramatic, judging by clinical observation, it offers more than other drug thus far tried. If by further orbitonome observations it can be shown that thyroid extract re does dependably lower intra-orbital pressure, such findi will be of great theoretical and practical interest.

Concentration of Thyrotropic Hormone

For the solution of the eye problem of Graves's dis and the larger one of the entire morbid state, determi tion of the concentration of thyrotropic hormones body fluids is obviously indispensable.

Rawson and Starr (1938) devised a fairly satisfacto method for urine, making use of the effect of inject material on the height of the thyroid cells in chic The very limited data which they have obtained indica that in thyrotoxic Graves's disease there is an increas excretion of thyrotropic hormone in the inactivat form.

De Robertis (1942, 1949) observed the rapid accumu tion of colloid droplets in the apices of thyroid ce after the injection of thyrotropic hormone, and u

st for thyrotropic hormone, finding a relation-
en the number of droplets and the amount
given. In the blood of patients with Graves's
found an excess in those exhibiting the
of progressive or malignant ophthalmopathy.
(1949) has revived and improved the well-
hibian-metamorphosis test, and believes that
can estimate the concentration of both the
and the thyroid hormones in the serum.
s tadpoles into a non-metamorphosing state
on, and then injects them intraperitoneally
st fluid—e.g., serum. Two observations are
: the effect on metamorphosis (growth of
ities) and the effect on the tadpole's thyroid
rotropic hormone causes metamorphosis and
y of the thyroid epithelium ; thyroid hormone
metamorphosis but it leads to atrophy of
epithelium. In normal people and in classic
isease D'Angelo finds little or no detectable
hormone in the serum. In hyperophthalmo-
ves's disease, on the other hand, D'Angelo
siderable amount of thyrotropic hormone in
Only a few observations have been made,
ar D'Angelo's and De Robertis's results seem

Sensitivity

ough the evidence is scanty, we may still be
to speculate on its possible significance. If
l gland and the orbit were targets to the same
none they would have to respond in parallel
l of tropic hormone in the blood, unless one
nderwent a change in end-organ sensitivity.
e two might develop a resistance to tropic
ot displayed by the other. Thus the thyroid
d become inactive while the ophthalmopathy
ing aggravated. But perhaps thyroid gland
are responding to different tropic hormones,
f secretion of which may vary independently.
hese questions we need more information not
ood titres of hormones but also on sensitivity
ns. Rawson and Starr (1938) have contributed
rmation on the sensitivity of thyroid to
hormone ; as I said before, they find that,
the thyroid cell, thyrotropic hormone becomes
l. Further, the cells of thyroids removed from
ith Graves's disease inactivate more thyro-
mones than do those of normal persons. No
ns of this kind have been made on patients
perophthalmopathic phase, because in such
arefully refrain from thyroidectomy. However
lly vitally needed is information on the sensi-
nd-organs to the thyroid hormone, and what
ermine it. Almost no facts on these important
ave yet been obtained. How actually does
ormone act on cells, and what potentiates or
uch action ? To these questions we badly
ers.

Gland

we hold that Graves's disease is a widespread
licated constitutional disorder, we may next
hat other endocrine glands besides the pituitary
hyroid are importantly involved in its morbid
m. The thymus is undoubtedly, but is that
rine gland ? We know nothing very definite
rôle of the thymus save that it is often some-
rged in Graves's disease. Selwyn Taylor tells
as fed five patients with Graves's disease on
ves' thymus and noted a fall in B.M.R. and
ent in symptoms, but the data are not sufficient
nclusive. Then there are the ancient claims
surgeons as von Harberer and Halsted that
my contributes some benefit. In passing we may note that the thymus plays a part in the alarm reaction of Selye ; so too does the adrenal cortex, which moreover, is a perfectly respectable endocrine gland. Therefore its rôle in Graves's disease may properly next concern us.

Adrenal Cortex

There is rapidly accumulating evidence of a vitally important balance between the thyroid gland and the adrenal cortex. The hormones of each appear to protect against ill effects of overproduction of the other. Thus Koelsche and Kendall (1935) found that adrenocortical hormones exert a sparing action against the negative nitrogen balance induced by thyroxine, and G. W. Thorn (personal communication) has found that rats made thyrotoxic with thyroid hormone lose less body-weight and show less increase in heart weight if given adrenocortical extract than do controls given thyroid hormone alone. Conversely, Zondek (1935) states that thyroidectomised animals survive total adrenalectomy longer than do those possessing thyroids, and it is well known clinically that patients with hypofunction of the adrenal cortex are far more sensitive to thyroid hormone than are normal persons.

The opportunities nowadays for studying the inter-relations of the thyroid gland and the adrenal cortex are abundant, because we have many tests for the functional activity of both these organs. The thyroid gland can be tested, for example, by its response to thyrotropic hormone, to iodine, and to anti-thyroid drugs, and the effect of thyroid hormone on targets as expressed by the B.M.R. We can also measure the avidity of the thyroid gland for iodine by observing its uptake of radioactive iodine. On the adrenal side, among other things, we can observe the responses to the adrenocorticotropic hormone, and we can identify steroids of adrenal origin in the urine.

I have long been curious about the function of the adrenal cortex in Graves's disease, and when, in 1945, the late Edwin J. Kepler spent six months in my clinic, I induced him to apply his water test of cortical function to patients with the thyrotoxicosis of Graves's disease. He did this in a few cases, but the results were equivocal. More recently the eosinophil has made its entry upon the adrenal stage as a good index of cortical function. The eosinophilic population of normal blood is 100–300 per c.mm. When cortical function increases through the impact of adrenocorticotropic hormone, there is a sharp fall in the eosinophil-count. One can give the hormone directly to man or animal, or one can stimulate the pituitary to increase its output of the hormone by giving adrenaline (epinephrine). If after the administration of either adrenaline or adrenocorticotropic hormone there is no fall in the eosinophil-count, the conclusion is that the cortex is capable of being stimulated.

Studies are under way in our clinic on the cortical function in thyrotoxicosis and in myxœdema, and of the effect of treatment in each, making use of the several methods of testing which I have mentioned. The data are only just being obtained. All that can now be said is that in untreated myxœdema the response to adrenaline is at or below the lower limit of normal, and in thyrotoxicosis the eosinophil-count, which before treatment runs in the low range of 30 per c.mm., rises during treatment with propylthiouracil to a normal range. It seems, then, that in myxœdema the cortex is underactive and in thyrotoxicosis, on the other hand, it is working overtime.

One is tempted to generalise that, when either adrenal cortex or thyroid gland increases or decreases its functional activity, the other does likewise in compensation. In addisonian anæmia there is characteristically a low B.M.R., and Thorn tells me that there is also a slow uptake of radioactive iodine—another manifestation of lowered thyroid function. When Kendall's Compound E is given in addisonian anæmia, the uptake of radioactive iodine becomes normal and the B.M.R. rises.

Thorn holds the theory that with waning cortical function there is an increase in lymphoid elements, and that these absorb thyrotropic hormone. In so far as they can compete with the thyroid for thyrotropic hormone they can spare the patient from the ill effects of thyroid hormone in the presence of low cortical function. Thus emerges a link between the lymphatic system and the suprarenal cortex, which in the face of the well-known lymphoid hyperplasia of Graves's disease seems to be pregnant with meaning, but to me at least this meaning still remains obscure.

One other item of Thorn's I regard as of extreme interest. In his large series of addisonian anæmia he finds a past history of Graves's disease significantly more often than in any random series of patients. I shall have to leave both thymus gland and adrenal cortex at that. Certainly they deserve intensive study in relation to Graves's disease from every possible angle.

Thyrotoxic Crisis

The thyrotoxic crisis, or thyroid storm, also deserves intensive study. This remarkable event in the course of Graves's disease was formerly far commoner than it is today and may be the "Open Sesame" to the conundrum of Graves's disease. The best guess that I can make about its significance is that it may represent what we may call decompensated Graves's disease. There is an acute failure in the ability of the body to adjust to the thyrotoxicosis; a breakdown occurs, with the fulminating development of hyperthermia. I can see some analogy between it and the hyperthermia of sunstroke. The opportunity to study thyrotoxic crisis but rarely presents itself, and when it does is apt to be lost, because so urgent is the patient's situation that all efforts are directed toward treatment, and investigation goes by the board. I urge any of those who encounter such cases to mobilise all aid possible and obtain all the facts possible about the levels of hormones and electrolytes in body fluids.

Thyroidectomy

As regards primacy, or lack of primacy, of the thyroid gland in Graves's disease, the usual effectiveness of ablation of that organ, whether by surgery, drug, or radiation, is intriguing. Many years ago J. de J. Pemberton, of the Mayo Clinic, remarked to me that the results of subtotal thyroidectomy were better than theoretically they should be. If the morbid cause is left behind, why does not the disease invariably recur after operation? Sometimes it does, but more often it does not. Pemberton suggested that a hormonic vicious circle has been set up in some way in Graves's disease and is broken by thyroidectomy, permitting restoration of normal hormonic balance. Linnell and Greene (1947) also, referring to Boon and to Fenz, introduce the possibility of a vicious circle; they include the hypothalamus, on which thyroxine may act directly. They make the following suggestion:

> "In thyrotoxicosis a hypersensitive hypothalamus, reacting to a normal blood thryoxine, causes, via the carotid plexus and the pituitary, a still greater output of thyroxine, thus initiating a vicious circle On this hypothesis it is easy to explain both the influence of mental strain in initiating the disease and the occasional cures produced in early primary cases by rest, psychiatric methods, or thiouracil. It is, on this hypothesis, improbable that a permanent cure could be produced in long-standing cases by any known means other than thyroidectomy."

I cannot believe, nor is it claimed, that this hypothesis has had adequate testing. It seems to me, however, worthy of investigation. If the primary fault in disease lies in an oversensitivity of the thyroxine, we must determine what causes sensitivity. Is it acquired or inherited?

Heredity

The rôle of heredity is indeed a high-priority To assess its importance we need the help of the cist, and a geneticist is already at work on the here at University College Hospital. Linnell and (1947), at the London County Council Thyroid have emphasised the importance of the genetic a to the ætiology of thyrotoxicosis, and Bartels favours the hypothesis that Graves's disease is a bance of balance in the relations between the the vegetative nervous system, and the pituitary, if I understand him aright, is essentially the theor I hold. He further believes that in many cases the must develop on the basis of an inherited defect, he thinks may reasonably be located in the Indeed, in his opinion Graves's disease is "alwa to a genotypic disposition."

Epidemiology

Another clue may lie, I believe, in the fact Graves's disease, at times, is epidemic. In his last on the Danish epidemic Meulengracht (1949) ind that the spot map of cases bears a striking resem to that of an infectious disease. He does not go as to conclude that Graves's disease is infectious he does submit that here is a resemblance which re explanation. I agree on this last point, but I c yet bring myself to believe that infection is a factor in Graves's disease.

CONCLUSION

I surmise that Graves's disease is somewhat anal to the adaptation syndrome of Selye (1946) except it is pathological. Perhaps tentatively we might a "maladaptation syndrome" and look on it type of response that persons of certain constitu pattern make when they encounter certain ad circumstances in living.

"... I detect in many doctors and many scientists a fai to achieve a corresponding stage of maturity in other re —political, social, cultural, religious, and esthetic. transfer value of achieving maturity in science and medi seems to be very slight indeed.... It is the proper destin man as a human being to achieve maximum maturity. medical profession has made notable strides in promoting exhibiting such maturity in dealing with bodily and men ailments, but no comparable advance has yet been ma toward a mature judgment on historical movements, econo forces, cultural values, moral responsibilities, and relig beliefs. Although this is the special responsibility of liberal arts teacher and scholar, medical schools are in responsible for developing this judgment."—Prof. T. GREENE, in *Trends in Medical Education* (Commonwea Fund, New York, 1949).

TUBERCULOSIS

ONTROL OF AN INFECTIOUS DISEASE

JOHN FRANCIS
B.Sc. Lond., M.R.C.V.S.

trol of tuberculosis in cattle has been described
(Francis 1947, 1949). I need only repeat here
a satisfactory means of diagnosis (the intra-
berculin test) was developed, eradication of
disease in any country has depended solely
termination of the veterinary profession to
interest of the farmers, obtain support from
ment, and guide the work along rational lines.
e not always been easy tasks. but tuberculosis
been eradicated from Finland, the Channel
vast area of the U.S.A., very largely from
d Sweden, and almost entirely from Denmark
to twenty years ago had an incidence similar
reat Britain). In this country there are already
cattle, out of 8–9 million, in Attested herds.
has the distinction of being the first Attested
there is little doubt that others will soon be
on the mainland.

e, because of the control that can be exerted
dividual animal and herd, the chain of infection
roken relatively easily, and immunisation is
s. In man, however, immunisation is the one
eans of increasing resistance to tuberculosis
reducing the number of clinical cases and
ersons. For this purpose B.C.G. vaccine has
lable for twenty-five years, but it has only
tly been used in Great Britain.

Efficacy of B.C.G.

ief opposition to the use of B.C.G. in Great
s come from G. S. Wilson (1947), and because
ensive knowledge of bacteriology and immunity
act that his conclusions have generally proved
d it is natural that his paper should have made
ple doubt whether it was worth using the
It is, however, not always realised in scientific
at it is at least as important not to be over-
s it is to guard against over-optimism.

n (1948) has dealt with Wilson's criticisms and
"although partly justified they are correct
unessentials and are in many respects erroneous
st; they do not give the impression of being
" Wallgren admits that in his own work the
t played by B.C.G. in the remarkable reduction
ity and mortality cannot be accurately assessed,
bservations show that "while primary pulmo-
rculosis in a child unvaccinated with B.C.G.
show any tendency towards radiographically
able regression during the first six months. in
ho has been vaccinated with B.C.G. and who was
rculin-positive at the time of infection radio-
veal that within this period the condition has
resolved." He continues:

> is also remarkable that I have not seen a single
> tely vaccinated child die from tuberculosis after
> been infected, nor have I observed a single case
> rculous meningitis among vaccinated children. Is,
> he scientifically calculated and statistically reported
> of immunity of such great import if the effect of the
> tion is satisfactory?"

ther Wallgren's reply nor the presentation of
other people (Tytler 1946) have overcome the
on created by Wilson's article; so it is necessary
amine his criticisms.

DIFFERING STANDARDS OF EVIDENCE

n's main thesis is that there are no adequate
ed trials with statistically significant results showing that B.C.G. is effective. If this criticism were true it would have some validity; but it should be pointed out that he adopts entirely different standards of evidence when discussing B.C.G. on the one hand and, say, pasteurisation or different methods of immunisation on the other. He has himself presented the evidence supporting the value of pasteurisation (Wilson 1942), and much of it is seen to depend on falls in the non-pulmonary death-rate when milk is heat-treated or when tuberculosis is eradicated from cattle. But it is well known that the proportion of tuberculosis deaths which are extrapulmonary varies independently of the incidence of infection in cattle. Wilson himself (1947) points out that in American Indians the ratio of non-pulmonary to pulmonary tuberculosis was 2½ : 1, whereas in the general population of the U.S.A. it was about 1 : 5; and as bovine tuberculosis has been eradicated from the U.S.A. the high incidence of non-pulmonary tuberculosis in the Indians can hardly be due to consumption of tuberculous milk. The above example is admittedly extreme, but it is well recognised that the morbidity and mortality of extrapulmonary tuberculosis become steadily less as the tuberculous epidemic progresses. In Australia, where bovine tuberculosis has never been a serious disease and hence no special precautions have been taken to prevent milk-borne infection (Wakefield Rainey 1944), extrapulmonary tuberculosis has diminished more rapidly than in other countries (Holmes 1937).

Admittedly some of the epidemiological evidence that pasteurisation reduces the mortality from extrapulmonary tuberculosis is very convincing, but it is no more convincing than the epidemiological evidence supporting the value of B.C.G., and Wilson (1942, p. 151) admits that it includes no really satisfactory controlled experiment. Hence it is hard to understand his advocacy of pasteurisation and opposition to B.C.G.

The more effective the measures taken to protect children from tuberculous infection, the more necessary does immunisation become to protect the tuberculin-negative adolescent (Birkhaug 1948). In Scandinavia the importance of infection from bovines has been recognised but not overestimated. The work of Hedvall (1942), Magnusson (1942), and especially of Sigurdsson (1945) has shown how the subject should be investigated—by obtaining the collaboration of veterinary surgeons and farmers and studying the epidemic at its source. Meanwhile pasteurisation of milk and eradication of bovine tuberculosis has proceeded in Denmark as a small part of an adequate programme to control human tuberculosis.

Wilson fears that B.C.G. vaccination may interfere with such highly reliable prophylactic measures as vaccination against smallpox and diphtheria. Scarcely anyone doubts the value of these measures; but does the evidence in their favour conform to the standards he demands for B.C.G.? The figures of Harries (1930) showing the results following diphtheria immunisation of the nursing and later the domestic staff of the Birmingham City Fever Hospital were quoted by Topley and Wilson (1946, p. 1397) as being the most convincing, and they doubtless provide very good "demonstrative evidence"; but they are no more a statistically satisfactory result of a controlled experiment than are the results of Wallgren and other Scandinavian workers (see Birkhaug 1948) following vaccination of nurses with B.C.G., or the fall in the death-rate from pulmonary tuberculosis in vaccinated but not in unvaccinated groups in Bornholm (see Malmross 1948).

> The same is true of *smallpox* vaccination: "The evidence that vaccination protects against smallpox is very strong, but unfortunately exact statistical evidence is difficult to obtain" (p. 1891).
>
> Similarly with *typhoid fever* in the first world war: "the exigencies of war, the impossibility of getting complete figures

for the inoculated and the uninoculated exposed to risk, and the fact that the proportion of inoculated men rose, in the British Army, to well over 90% by the end of 1915, rendered impossible the collection of mass figures of a kind suitable for detailed statistical analysis. The general trend of the evidence is not, however, in doubt" (p. 1551).

Discussing plague vaccination Topley and Wilson say that "the results are necessarily difficult to interpret, since it is impossible to know what fall in mortality would have occurred in the absence of vaccination. The fall, however, in this instance was remarkably rapid, and the figures taken in conjunction with those of Table 154 suggest strongly that vaccination played a not unimportant part." Again, in Madagascar, "as in Java, the fall after vaccination was started appears to have been greater than would have been expected in its absence" (p. 1645).

Even with such a potent antigen as tetanus toxoid, "owing to the low incidence of tetanus in peace-time, the efficacy of active immunisation has been for the most part judged by the antitoxin response in the inoculated subject, and it is only in the last few years that *indications* of its prophylactic value have been obtained" (p. 1765).

No reasonable person doubts the value of all the above measures, but as it will be shown later that B.C.G. vaccination is the one immunological procedure in man about which there is satisfactory statistical evidence it is very difficult to understand the stubborn opposition to its general use.

CONTROLLED TRIALS WITH B.C.G.

The results of a number of controlled trials are shown in the accompanying table. The observations of Hyge (1947) deal with a natural epidemic rather than a controlled trial, but this does not reduce their significance.

He described an epidemic of tuberculosis in a school for girls aged 12–18 years: 105 pupils were tuberculin-positive before exposure, 106 were vaccinated with B.C.G., and 94 were tuberculin-negative. The source of infection was a temporary teacher who visited the school for only a limited time. The duration of exposure was two months in all three groups. The pupils were followed up during the first three years after exposure. Of the tuberculin-positive group only 2 had fallen ill with pulmonary tuberculosis during the period of observations, of the B.C.G.-vaccinated group 2 contracted pulmonary tuberculosis and were in need of pneumothorax treatment. Of the tuberculin-negative group 41 fell ill with tuberculous disease; 1 of them died and 5 others needed treatment with pneumothorax. The morbidity-rates in the three groups were 1·9, 1·9, and 43·6% respectively.[1]

In the other experiments every precaution appears to have been taken to make the groups comparable.

Nieman and Loewinsohn (1947) carried out a trial in which 1417 *children were vaccinated 4–6 days after birth; 1414 children* were not vaccinated and served as controls. All the children came from homes free from tuberculosis, as proved by chest radiography, but they lived in an area of Chicago with a high tuberculosis mortality-rate. The groups included negro and white children and paired subgroups were observed for intervals varying from three months to nine years. A primary complex was demonstrated by X rays in 14 vaccinated and 42 unvaccinated children.

Ferguson and Simes (1949) carried out a trial in Indians: families of comparable status in respect of housing, sanitation, and certain other economic and social factors likely to affect the health of children were paired, and one member of each such pair was allotted at random to one of two groups, designated A and B. All children born into the families of group A were vaccinated in one year, while all children born into families of group B in the same year were taken as controls. In the following year this situation would be reversed, and so on throughout the duration of the study. This procedure resulted over a period of years in groups of 306 vaccinated and 303 unvaccinated, which were balanced in respect of both age and environmental factors considered. The trial has lasted fourteen years and 2 vaccinated and 9 control children have died from tuberculosis; all other manifestations of disease have shown about the same relationship.

* Figures in bold type indicate deaths from tuberculos

No data in any way comparable with those shown in t are quoted by Topley and Wilson (1946) to support the any one of the commonly used immunological procedures. T two studies shown above had not been published when article appeared, and only a preliminary announcement of results had been made.

Aronsen and Palmer (1946), and Aronsen (1948) reported a trial in which children in Indian reservations who failed to react to tuberculin were divided into groups on an age-and-sex basis. One group was intradermally with saline and the other with va The study was begun in 1936 and ten years 1550 vaccinated children and 52 of 1457 control chi had died of tuberculosis. The possibility of this being due to chance is about 1 in 10,000, and W goes so far as to admit that the figures are "very st tive"; but he adds that "it may be questioned wh the conclusions drawn from them can legitimate transferred to civilized peoples having a higher d of genetic immunity and exposed, as a rule, to a risk of infection." He says it may perhaps be w remember the law of diminishing returns. It may be well to remember some of the laws of immuni as set forth by Topley and Wilson (1946). They p the well-known evidence that an animal often res much better to a second dose of antigen than t first—i.e., a slight immunity increases the response given dose of antigen. In the production of dipht antitoxin it is recognised that horses having natural antibodies respond much better than having none; but, quite apart from this, Kayne (has suggested, with very good reason, that the diffe between "primitive" and "civilised" persons in response to tuberculosis is that civilised races ha much greater ability than primitive to develop a sp *active resistance to tuberculosis.* Nieman and Loewin (1947) apparently observed no difference in the resp of white or negro children, and there is ample evid from Scandinavia that Europeans do respond sati torily to B.C.G. Therefore, in direct contrast to Wil suggestion, the evidence indicates that civilised viduals would respond at least as well to B.C.G. a primitive. It is, in fact, pointed out by Topley Wilson (1946) that the allergic state is advantageou European nurses but not to African miners.[2]

EVIDENCE FROM ANIMAL EXPERIMENTS

Before discussing this subject one must pay a tri to the basic pioneer work of *Calmette* and Gué Although the significance of their observations on is still disputed, their original ideas and experime on animals laid the *foundation* on which all subsequ work has been built. There is good experimental evide that B.C.G. produces an increased resistance to inva by tubercle bacilli in every species adequately studi It also produces allergy, and so far as I am aware allergy, in experimental animals, has always b associated with immunity. The fact that allergy m later be reduced or abolished without abolishing immunit does not invalidate the truth of the above statemen

---

[1] For more recent observations on these girls see *Lancet*, Aug. 13, p. 291.

[2] A fallacy in the last part of this statement is discussed b

terion of successful B.C.G. vaccination is the
nent of a positive tuberculin reaction, and if
e not associated with an increased resistance in
it is in all other animals, it would be one of the
culiar facts in comparative pathology. All our
ge of the pathogenesis and epidemiology of
osis in man does, however, support the view
allergic individual has a heightened resistance
enous reinfection. There are therefore very
reasons for assuming that we have direct
ental evidence of increased resistance in every
ed person who becomes tuberculin-positive.

y and its relation to immunity in tuberculosis is
l at some length by Topley and Wilson (1946).
ng the disease in European nurses and African
s, they admit that, in the heavily infected
nent of the hospital the advantage is with the
person, but they say that in the less heavily
but physically strenuous conditions of the mine
actory the advantage is with the non-allergic.
statement is true, but it involves a confusion
ht: the allergic native is allergic because he is
ing virulent tubercle bacilli, and although he can
this infection fairly well when living in his kraal
ot control it under the adverse conditions of mine
The allergy produced by B.C.G. obviously does
end on the presence of virulent tubercle bacilli
ody.

n this section on the efficacy of B.C.G. by quoting
n's (1948) clinical impressions, and I may perhaps
e by quoting those of Dorothy Price (1949), who

> my mind, B.C.G. offers a simple solution to the
> m of the infant of tuberculous parents. This vaccina-
> ith avirulent bacilli produces in a safe situation,
> y the skin, a minimal primary complex, which is
> enough to produce a tuberculin allergy and afford
> nity against subsequent exogenous re-infection, . . .
> ld say of our Dublin infants in the first year of life
> re exposed in the home to an open case of tuberculosis,
> ver 90% contract the disease; of these 41% die and
> ccupy treatment beds for one to three years. With
> ative vaccination the stay is six weeks in a maternity
> al or three months in a children's institution, or if

> ying the Swedish vaccine, I would offer 90% security
> t the development of tuberculosis, and the death-rate
> ligible."

t Justifiable to Prohibit the Use of B.C.G.?

ssing the Medical Research Council trial, the
Medical Journal (Editorial 1949a) doubts the
justification of returning unvaccinated children
rculous homes. Is it then justifiable to expose
lin-negative girls to tuberculous patients in
o obtain "statistically satisfactory evidence" on
ue of B.C.G.? Such an action would be considered
sible in every country that has experience of using
and one is glad to note that there are hospitals
t Britain where tuberculin-negative girls are not
to nurse tuberculous patients.

safety of B.C.G. vaccine has been fully established
1946, Holm 1946) and the evidence of its efficacy
ably better than that for any other vaccine. In
ht of these facts, and since in this country many
s but probably ineffective proprietary medicines
purchased, it is very difficult to see on what ethical
s those who wish to use B.C.G. are prevented from
ng.[3] Twenty-five years ago there would have been
ation for intensive work on the standardisation
vaccine and on controlled trials, but this work
w been done for us.

Natural History of Tuberculosis and Methods of Control

William Budd (1863), one of the pioneer epidemiologists, advised his medical colleagues to study natural epidemics in animals in order to throw light on human epidemics. During the first decade of the 19th century there were people who believed that tuberculosis in cattle could be controlled by raising "healthy" cattle that would not develop tuberculosis.[4] This method never met with success, but it has become abundantly clear that when all efforts are concentrated on breaking the chain of infection eradication can be achieved relatively quickly and over vast areas.

Some people believe that civilised men must learn to live with the tubercle bacillus; and it is of course true that a group of persons with healed primary complexes withstands subsequent exogenous infection better than an uninfected group—though it should be remembered that they are already a selected population. But the danger to which a population of "healthy reactors" are exposed is well shown by events during the two world wars, when lowered resistance and increased stresses of various sorts caused many such persons to die of active tuberculosis (Wolff 1940, Long 1942, Bruns 1920). In fact, anyone who regards the "satisfactory" development of a primary complex as desirable is in the same position as those who regard tubercle bacilli in milk as desirable. The dangers of these "methods of immunisation" are well illustrated by the cases of acute tuberculosis in children, and in adolescents who are exposed to infection when still tuberculin-negative.

Wilson says that if "minimal pulmonary, glandular, and other manifestations of tuberculosis are included in the results of trials it may be possible to swell the number of tuberculous cases in the control group, as in Heimbeck's (1936) figures, and make out a theoretically convincing but practically unimportant case for B.C.G. vaccination." In view of the facts I have mentioned this attitude is surely open to question. In addition, all the work on the control of tuberculosis in cattle shows that, for success, tuberculosis must be regarded as an infectious disease, and Myers (1946a and b) has rightly emphasised the fallacies of disregarding "healthy reactors" in man: every person with phthisis was once a "healthy reactor."

The eradication of human tuberculosis is obviously much more difficult and complex than the eradication of bovine tuberculosis, but it has recently been pointed out (Editorial 1949c) that less attention has been paid to the control of human tuberculosis than to its clinical study and treatment. This appears to be generally true: thus Ryle (1948) writes:

> "The morbid 'material' of the hospital ward (sanatorium) consists very largely . . . of end-result conditions for which, as a rule, only a limited amount of relief repays the long stay, the patient investigation, and the anxious expectancy of the sick man or woman. With ætiology—the first essential for prevention—and with prevention itself the majority of physicians and surgeons have curiously little concern."

Again, Ryle says that the *living* human community has been insufficiently considered as an object worthy of study.

It appears that in Great Britain more interest has been taken in the clinically tuberculous person in the sanatorium than has been taken in epidemiological studies and preventive work of the type reported by Sigurdsson (1945), Holm and Holm (1945), Madsen et al. (1942), and Olsen (1943). British veterinarians, on the other hand, while paying little attention to the clinical study

---

ent memorandum from the Ministry of Health (*Lancet*,
ly 2, p. 29) indicates that the vaccine will be more generally
ailable than was supposed when this paper was written.

[4] This conflict in the human field is illustrated by Editorials (1949b and c) and by Wingfield (1942). Paterson (1947) has given an interesting account of other conflicts which may arise in course of work on the control of tuberculosis.

of the individual (apart from diagnosis) or to the treatment of tuberculosis, have studied the living animal community—the problems of infection and control—and they have eradicated tuberculosis from many thousands of herds.

Wilson believes in pasteurising milk because he believes it will prevent about 40% of the mortality from tuberculosis in infants.[5] Yet, even when he assumes for the purpose of argument that B.C.G. does afford some measure of protection, he doubts whether it is worth using, and puts forward seven points of difficulty against its adoption. These points have already been met by Wallgren, and since the difficulties were overcome in Norway during enemy occupation, surely we in Great Britain need not be overwhelmed by them now?

One cannot help feeling that even the staunchest supporters of B.C.G. have been too much impressed by the critics and too much on the defensive. At the same time it should be made clear that I do not expect B.C.G. to produce such striking results as those obtained with some other immunological procedures, and there are limits to its usefulness. Medlar (1948) has rightly remarked that although it is of value in reducing the severity of primary tuberculosis and the progressive tuberculosis that develops soon after primary tuberculosis in young adults, its effect on tuberculosis of the "reinfection" type in older persons must be less. But if one belongs to the "endogenous" school one must assume that anything which reduces the severity of the primary lesion will reduce its tendency to exacerbate in later years.

The whole subject of primary infection and reinfection has been fully discussed by Pagel (1948), who showed that phthisis may sometimes develop at an early stage from a primary cavity. Myers (1946a) contended that primary infection is nearly always benign and anything which follows the primary lesion is due to "reinfection" in a dangerously allergic soil; but Malmross (1947) points out that it would be just as reasonable to say that a primary syphilitic lesion is harmless. He cites the evidence that in young adults progressive tuberculosis not uncommonly develops in close connexion with the primary infection, and the evidence that B.C.G. affords considerable protection against this sequence. It is interesting that in a later paper Myers (1947) says that he will be prepared to use B.C.G. when its efficacy is "proved," though he emphasises the good results he has obtained by using fundamental, well-established methods of control.

The Importance of Tuberculosis and Its Eradication from Human Communities

Wilson states that during the whole Prophit survey, which lasted for ten years, only 2 nurses died of tuberculosis, and he seems to imply that the disease is not important in nurses. But the fact that tuberculin-negative nurses, medical students, and young physicians are particularly liable to develop tuberculosis is established beyond dispute (Holm 1941, Topley and Wilson 1946). The *British Medical Journal* (Editorial 1947) notes that in the Prophit survey

> "the number *initially Mantoux-negative* was 452, and of these no fewer than 33 (7%) developed clinical tuberculosis. It is true that only 2 of these nurses had died when the report was written, but 2 had spinal caries, 1 advanced tuberculous laryngitis, and 4 others active pulmonary disease; in the remainder the lesion was stated to be 'arrested,' 'quiescent,' 'healed,' or 'recovered,' but any such description can be only provisional in this Of the originally Mantoux-positive 2120 nurses —a much lower proportion—had developed tube the disease was still active in 14 and 'quiescent' in the number of deaths in this series could be sta or even twenty years hence the picture would different: tuberculosis is a disease which takes a lo to kill. For the same reason the fact that only 1 1740 dies of tuberculosis in the first year of life d present a true picture of the mortality from n acquired at this time."

One may gain the impression from Wilson's that tuberculosis is a relatively unimportant and that even if B.C.G. were effective it would ha worth going to the trouble of producing and admin the vaccine. Yet the tubercle bacillus kills 400 in every week in England and Wales (which is mo are killed in all fatal accidents), and if the age at death occurs is taken into account it is more im than any other single cause of death (Stocks 1949). makes it all the more curious that since about 1915 the publication of the reports of the Royal Com the proper study of tuberculosis in Great Britain been sadly neglected. The important investi on pathology have been made in Germany and in America. Research into the chemistry of the tu bacillus, and research leading to the first succ chemotherapy, have been done in America. thorough work on epidemiology and bovine-type inf has been done in Scandinavia, and, above all, the on immunisation (if one excludes that on catt Great Britain) has been done in France and lat Scandinavia.

Myers (1946b) has been much influenced by the on the control of bovine tuberculosis; he has the tuberculin test in diagnosis and in assessing efficiency of his attempts to reduce the spread of infect In 1920, when he began his studies, the death-rate f tuberculosis in Minneapolis was 120 per 100,000, wh was greater than that for the U.S.A. as a whole; in 1945 it was 27·1 against 40 for the U.S.A. The num of tuberculin reactors in grade-school children reduced from 50% in 1926 to 8% in 1944, and M (1947) reported that there are now large areas in wh tuberculosis has been completely eradicated at grade-school age-level. Work on similar lines has b carried out in Scandinavia. In Bornholm tuberc negative populations are being created (Olsen 1 and Holm and Holm (1945) believe that with "roentgen bus" per 150,000 persons tuberculosi a national ailment could be eradicated in ten to fi years with the aid of B.C.G.[6] The situation in Br presents an unhappy contrast: "mass-radiography languishing for want of an idea as to how it sho be used and the advocates of B.C.G. vaccination h received on the wireless and in the press the disheartea concession that it shall be permitted in a clinical t on a '*few thousand volunteers*'" (Editorial 1949c).

Need for a New Sanitary Revolution

Both in the animal and human field, Great Brit led the way in the great sanitary revolution which be about 1850; but when the time came to deal wi tuberculosis much of our energy seems to have fa and the lead was taken by other countries. Veterinar and farmers have now decided that tuberculosis shall b eradicated from the cattle of Great Britain and a well on the road to achieving this in ten to twenty yea time. It would be appropriate if another sanitar revolution could be begun just a hundred years after th first, which would lead to the virtual eradication of hum tuberculosis. The control of the last of the great zymo diseases of man in Great Britain might well be sk of the new social medicine advocated by Ryle. on harbouring tubercle bacilli would then be upon in the same light as a carrier of typhoid se of smallpox.

---

[5] It has been suggested elsewhere (Francis 1949) that the total effect of pasteurising milk may be to increase the total mortality from tuberculosis, because alimentary infection acquired from drinking milk is usually mild, and it appears to immunise against the more serious respiratory infection. It does not follow that we should fail to make milk safe: it does follow that more effective methods should be used to protect against human tuberculous infection.

[6] Birkhaug (1948) has pointed out that B.C.G. becomes more, less, important as tuberculosis is controlled.

ognise that there are many difficulties to over- efore this aim is achieved, but it will never be d unless clearly envisaged and worked for. What ired now is not a "statistically satisfactory trial" ., but the imaginative leadership of a campaign ch all weapons—tuberculin-testing, mass radio- , clinical treatment (including chemotherapy), munisation with B.C.G.—will be used in an attempt uce mortality from the most important single f death in Great Britain.

Summary

ork on tuberculosis in cattle shows that the can be controlled over large areas when the ilin test is used as a diagnostic agent and all are concentrated on breaking the chain of n.

he control of human tuberculosis is obviously more complex, because far less control can be over the individual. Though chemotherapy entually come to play an important part, B.C.G. one specific weapon that can now help to reduce mber of infected persons and the severity of new ns.

C.G. has been available for twenty-five years, have done almost no work in Great Britain on ndardisation of the vaccine or methods of using it .

here still appears to be little official enthusiasm use of B.C.G. in Great Britain.

uite different standards of evidence are used when iscussing the value of B.C.G. and when discussing e value of other immunological procedures or of asteurisation.

is stated that there are no properly controlled trials emonstrating the value of the vaccine in man. This atement is unjustified. The suggestion that civilised ces will not respond to B.C.G. as well as native races spond also has little foundation: indeed the reverse more probably correct.

here is abundant evidence that B.C.G. increases ce to tuberculosis in experimental animals, and creased resistance is for all practical purposes ted with the development of allergy. An allergic e is the criterion of successful B.C.G. immunisation, ere are very good reasons for regarding allergy munised persons as direct practical proof of ed resistance.

here seems to be no justification for withholding vaccine from people who want to use it or for g tuberculin-negative girls to tuberculous patients er to obtain statistically satisfactory evidence of ue. The evidence supporting the use of B.C.G. dy better than the evidence supporting any other ological procedure in man. Data collected in indicate that B.C.G. may cause a fivefold reduction morbidity and mortality of tuberculosis, which be well worth achieving if only for the ny it would mean in surgical and sanatorium ent.

eterinarians and farmers have decided that bovine ulosis shall be eradicated in ten to twenty years. n tuberculosis remains the most important single of death in this country. What is required t so much an "adequate trial" of B.C.G., campaign which will begin a new "sanitary tion" and control of the last of the great ic diseases in Great Britain.

SEQUELÆ OF INFECTIVE HEPATITIS IN CHILDREN

REVIEW OF TWELVE CASES

W. G. WYLLIE
M.D. Edin., F.R.C.P.
PHYSICIAN, HOSPITAL FOR SICK CHILDREN,
GREAT ORMOND STREET, LONDON

MARGARET E. EDMUNDS
M.B. Lond., M.R.C.P., D.C.H.
RESEARCH ASSISTANT, INSTITUTE OF CHILD HEALTH; LATE
MEDICAL REGISTRAR AT THE HOSPITAL

MANY recent reports have drawn attention to the relatively high incidence of cirrhosis following infective hepatitis among adults, especially troops, during the war years. Records of chronic hepatic damage, possibly leading to a fatal termination, among children are scarce. The power of hepatic regeneration may be greater in childhood than in adult life, yet the present series of cases with sequelæ is composed of twelve children aged $3^1/_2$–12 years; all except one were seen between 1942 and 1945, and six died.

Epidemics of infective hepatitis chiefly affecting children have been recorded, in this country, by Pickles (1930), Glover and Wilson (1931), Montford (1934), and Frazer (1935). There were no fatalities, and apparently all recoveries were complete, though Pickles mentions one patient who did not recover for two months. Commenting on these, Barber (1937) remarked that infective hepatitis was most infectious to children, the majority of whom recovered completely, but that "these apparently simple cases of jaundice should be treated

Wingfield, R. C. (1942) *Proc. R. Soc. Med.* 36, 39.
Wolff, G. (1940) *Amer. Rev. Tuberc.* 42, 1, 214.

of the individual (apart from diagnosis) or to the treatment of tuberculosis. have studied the living animal community—the problems of infection and control—and they have eradicated tuberculosis from many thousands of herds.

Wilson believes in pasteurising milk because he believes it will prevent about 40% of the mortality from tuberculosis in infants.[5] Yet, even when he assumes for the purpose of argument that B.C.G. does afford some measure of protection, he doubts whether it is worth using, and puts forward seven points of difficulty against its adoption. These points have already been met by Wallgren, and since the difficulties were overcome in Norway during enemy occupation, surely we in Great Britain need not be overwhelmed by them now?

One cannot help feeling that even the staunchest supporters of B.C.G. have been too much impressed by the critics and too much on the defensive. At the same time it should be made clear that I do not expect B.C.G. to produce such striking results as those obtained with some other immunological procedures, and there are limits to its usefulness. Medlar (1948) has rightly remarked that although it is of value in reducing the severity of primary tuberculosis and the progressive tuberculosis that develops soon after primary tuberculosis in young adults, its effect on tuberculosis of the "reinfection" type in older persons must be less. But if one belongs to the "endogenous" school one must assume that anything which reduces the severity of the primary lesion will reduce its tendency to exacerbate in later years.

The whole subject of primary infection and reinfection has been fully discussed by Pagel (1948), who showed that phthisis may sometimes develop at an early stage from a primary cavity. Myers (1946a) contended that primary infection is nearly always benign and anything which follows the primary lesion is due to "reinfection" in a dangerously allergic soil; but Malmross (1947) points out that it would be just as reasonable to say that a primary syphilitic lesion is harmless. He cites the evidence that in young adults progressive tuberculosis not uncommonly develops in close connexion with the primary infection, and the evidence that B.C.G. affords considerable protection against this sequence. It is interesting that in a later paper Myers (1947) says that he will be prepared to use B.C.G. when its efficacy is "proved," though he emphasises the good results he has obtained by using fundamental, well-established methods of control.

The Importance of Tuberculosis and Its Eradication from Human Communities

Wilson states that during the whole Prophit survey, which lasted for ten years, only 2 nurses died of tuberculosis, and he seems to imply that the disease is not important in nurses. But the fact that tuberculin-negative nurses, medical students, and young physicians are particularly liable to develop tuberculosis is established beyond dispute (Holm 1941, Topley and Wilson 1946). The *British Medical Journal* (Editorial 1947) notes that in the Prophit survey

> "the number initially Mantoux-negative was 452, and of these no fewer than 33 (7%) developed clinical tuberculosis. It is true that only 2 of these nurses had died when the report was written, but 2 had spinal caries, 1 advanced tuberculous laryngitis, and 4 others active pulmonary disease; in the remainder the lesion was stated to be 'arrested,' 'quiescent,' 'healed,' or 'recovered,' but any such description can be only provisional in this Of the originally Mantoux-positive 2120 nurses —a much lower proportion—had developed tu the disease was still active in 14 and 'quiescent' in the number of deaths in this series could be sta or even twenty years hence the picture would different: tuberculosis is a disease which takes a lo to kill. For the same reason the fact that only 1 1740 dies of tuberculosis in the first year of life d present a true picture of the mortality from acquired at this time."

One may gain the impression from Wilson's that tuberculosis is a relatively unimportant and that even if B.C.G. were effective it would ha worth going to the trouble of producing and admin the vaccine. Yet the tubercle bacillus kills 400 in every week in England and Wales (which is mo are killed in all fatal accidents), and if the age at death occurs is taken into account it is more im than any other single cause of death (Stocks 1949 makes it all the more curious that since about 1915 the publication of the reports of the Royal Comm the proper study of tuberculosis in Great Britai been sadly neglected. The important investig on pathology have been made in Germany and in America. Research into the chemistry of the tu bacillus, and research leading to the first succ chemotherapy, have been done in America. thorough work on epidemiology and bovine-type inf has been done in Scandinavia, and, above all, the on immunisation (if one excludes that on catt Great Britain) has been done in France and lat Scandinavia.

Myers (1946b) has been much influenced by the on the control of bovine tuberculosis; he has the tuberculin test in diagnosis and in assessing efficiency of his attempts to reduce the spread of infec In 1920, when he began his studies, the death-rate f tuberculosis in Minneapolis was 120 per 100,000, w was greater than that for the U.S.A. as a whole; *in 1945 it was 27·1 against 40 for the U.S.A.* The num of tuberculin reactors in grade-school children reduced from 50% in 1926 to 8% in 1944, and M (1947) reported that there are now large areas in w tuberculosis has been completely eradicated at grade-school age-level. Work on similar lines has b carried out in Scandinavia. In Bornholm tuber negative populations are being created (Olsen 1 and Holm and Holm (1945) believe that with "roentgen bus" per 150,000 persons tuberculosi a national ailment could be eradicated in ten to fi years with the aid of B.C.G.[6] The situation in Br presents an unhappy contrast: "mass-radiography languishing for want of an idea as to how it sho be used and the advocates of B.C.G. vaccination h received on the wireless and in the press the disheartenı concession that it shall be permitted in a clinical t on a 'few thousand volunteers'" (Editorial 1949c).

Need for a New Sanitary Revolution

Both in the animal and human field, Great Brit led the way in the great sanitary revolution which beg about 1850; but when the time came to deal wi tuberculosis much of our energy seems to have fad and the lead was taken by other countries. Veterinari and farmers have now decided that tuberculosis shall b eradicated from the cattle of Great Britain and ar well on the road to achieving this in ten to twenty year time. It would be appropriate if another sanitar revolution could be begun just a hundred years after th first, which would lead to the virtual eradication of huma tuberculosis. The control of the last of the great zymot diseases of man in Great Britain might well be th ayed recovery of the liver; (2) compensated s; and (3) compensated cirrhosis in a possible eric case.

---

[5] It has been suggested elsewhere (Francis 1949) that the total effect of pasteurising milk may be to increase the total mortality from tuberculosis, because alimentary infection acquired from drinking milk is usually mild, and it appears to immunise against the more serious respiratory infection. It does not follow that we should fail to make milk safe: it does follow that more effective methods should be used to protect against human tuberculous infection.

[6] Birkhaug (1948) has pointed out that B.C.G. becomes more, less, important as tuberculosis is controlled.

DELAYED RECOVERY

7.—A girl aged 6 years in April, 1943, when first seen, eptember, 1942, been off her food and sick, and had jaundiced at the end of about a week. She had d but subsequently had recurrent attacks of nausea, e, and sometimes a yellow colour lasting for 2–3 Her urine contained bile. The edge of her liver three finger-breadths below the costal margin; her as not palpable: she was apparently in good health: m-bilirubin level was 0·6 mg. per 100 ml., and a reaction was strongly positive. In June, 1943, was clinically normal, and her Takata ±.

8.—A girl, aged 3 years, had vomiting, abdominal d dark urine, and became jaundiced for 2 weeks in 1942. Intermittent bouts of abdominal upset d. She was again jaundiced in May, 1946, and had r relapse in June. The symptoms all disappeared. December, 1946, her liver was "only just palpable." en was not felt, and the child appeared to be in good

possible that some cirrhosis may be present, in clinical and biochemical recovery, in cases 7 and 8.

COMPENSATED CIRRHOSIS

9.—A boy, aged 5 years, was first seen on Jan. 20, ith 10 days' history of malaise, frequent vomiting, ndice, dark urine, pale stools, one hæmatemesis, and staxis. After admission his temperature ranged to 103°F for a fortnight. He was drowsy and had y reddish-purple rash on his arms and face for 4 days. r and spleen were both firm and enlarged. He had contact with infective hepatitis at school. He had able anæmia: Hb 56%, red cells 3,600,000 per c.mm. dice lasted 3 weeks, but the liver and spleen were still l enlarged when the patient was discharged home in 43.

s readmitted subsequently five times up to January, ith bouts of vomiting and diarrhœa, or headache, s, and hæmatemesis, or pyrexia and abdominal Latterly the liver was recorded as "small" and the s just palpable. The patient has subsequently gone ica and is said to be in good health.

10.—A boy, aged 2½ years when first he became d in September, 1944, had had a normal infancy. ls were pale, urine dark, liver enlarged down to the s, and spleen palpable. The jaundice disappeared, Takata-Ara test was strongly positive in October, n December, 1944, the patient had a relapse, with ance of jaundice for a short time. On subsequent tions up to December, 1948, his liver and spleen were n and enlarged; he has had occasional epistaxes aid to be lively and well. A Takata reaction on 1948, was negative.

11.—A girl, aged 10 years, first seen in 1943, had had t attacks of abdominal pains associated with vomiting e stools for 5 years. She was slightly jaundiced and ow conjunctivæ; her urine contained bile. After a eal she had considerable abdominal pain. A chole- m was negative. The edge of her liver was not felt, derness was present in her right hypochrondrium. rum-bilirubin level was 3·2 mg. per 100 ml.; it ed to 1 mg. per 100 ml., and the jaundice disappeared. ata reaction changed from + + to ±. Since leaving the patient has not been traced.

SEQUEL IN A POSSIBLE NON-ICTERIC CASE

12.—A girl, aged 6 years, sister to six healthy children, ed in 1943 to be developing considerable enlargement abdomen, the firm rounded edge of her liver being lt, and her spleen palpable on inspiration. Laparotomy n done at another hospital a month before she was e, and "cirrhosis of the liver" had been found out 1½ pints of straw-coloured fluid. There was no d on admission here, and she had never been yellow. ssermann reaction and Mantoux test were negative, e Takata-Ara + +. Since discharge the child s well, and was last seen on Jan. 10, 1949, when her liver was enlarged and hard, the tip of her spleen palpable, and the Takata reaction ±.

The condition in cases 6 and 12, both with non-icteric onset, can, we think, be related tentatively to a preceding attack of subclinical infective hepatitis.

DISCUSSION

In our cases of compensated cirrhosis we have been unable to obtain serial estimations of the indirect van den Bergh and other tests of hepatic function. Altschule and Gilligan (1944) found some residual enlargement of the liver and a raised serum-bilirubin level in nine of thirty-six unselected patients examined 1–29 years after acute infective hepatitis.

As regards prognosis, we have found no means of telling, during the initial illness, whether an individual patient is going to do well or badly. Biochemical tests of liver function have not been found to help in this respect. This is in accordance with Sherlock's (1948) findings, though Roholm and Iversen (1939) have found that a strongly positive Takata-Ara reaction early in the disease is of some significance.

The clinical picture, again, gives no indication of the outcome. In all but two cases nausea, vomiting, or abdominal pain preceded the jaundice. In case 1 the jaundice preceded the intestinal symptoms by some days, but this has not been so in the other reported cases of acute yellow atrophy in infective hepatitis. In case 10 also the jaundice came first.

Ascites, though indicating severe liver damage, is not necessarily associated with a fatal outcome. It occurred in three fatal cases and one non-fatal case in this series. Other cases of recovery following ascites are reported (Sherlock 1948). Lucke (1944) reports its occurrence in the final phase of two-thirds of his series of 125 fatal cases.

It is not clear why ascites develops. Cullinan (1936) assumes that it is due to portal obstruction, since some patients also had melæna and hæmatemesis. This does not seem to be the entire explanation, since it occurs in the absence of other obstructive signs. Lucke suggests that it may also be due to a change in the plasma-proteins or to interference with the water-storage capacity of the liver. Fearnley's (1947) case is interesting in that the ascites was reduced by giving intravenous plasma-protein, even after the serum-protein level had been restored to 7 g. per 100 ml.

SUMMARY

The relation of chronic hepatic damage to infective hepatitis in children is discussed.

Twelve cases of infective hepatitis are reported, six of them fatal, to illustrate the possible sequels.

There is apparently no means of telling, in the initial attacks of jaundice, which patient will recover and which will not.

We acknowledge our thanks to Dr. W. W. Payne for his help in the biochemical studies.

with respect." In the past, death in childhood from infective hepatitis has been rare. One case, in a girl aged 11 years, is described by Morgan and Brown (1927), and another, in a girl aged $3^{1}/_{2}$ years, by Findlay and Dunlop (1932). Both of these showed acute yellow atrophy. There is some evidence that in recent years the virulence of infective hepatitis has increased, possibly aided by amino-acid deficiencies in war-time diet (see Himsworth and Glynn 1944) and by mixing and concentration of groups of the population. THE LANCET (1948), discussing the sequels, puts the case-mortality of epidemic jaundice at about 1 in 500, possibly higher, and reaffirms that it is a condition never to be taken lightly.

It seems to be possible for chronic liver damage to follow non-icteric attacks of infective hepatitis (Lawrence 1946, Kelsall et al. 1947). The apparent clinical severity of the initial attack certainly bears no relation to the likelihood of sequelæ.

It has been established by aspiration biopsies (Roholm and Iversen 1939, Dible et al. 1943) that the primary lesions of infective hepatitis are periportal cellular infiltration and hepatic-cell degeneration or necrosis beginning in the centre of the lobule. In severe cases, widespread necrosis or yellow atrophy occurring early may end fatally or may be compensated for by multiple nodular hyperplasia. In such cases a later decompensation may terminate in a recurrence of acute or subacute necrosis.

The late effects, based on Sherlock's (1948) aspiration biopsy and necropsy material and on the necropsy findings of Lucke (1944) and Cullinan (1936), may be graded as follows:

(1) Complete restoration of the hepatic lobule, provided its reticulin framework is undamaged.

(2) Periportal (zonal) fibrotic scarring, which usually disappears or may be progressive.

(3) A fine diffuse portal cirrhosis, which may be obstructive, leading to gastric or œsophageal hæmorrhages.

(4) Multiple nodular hyperplasia replacing massive necrosis.

(5) Acute or subacute liver necrosis ending in one of the chronic forms.

According to Lucke (1944), histological signs of regeneration begin to appear about the tenth day of the illness, and it is interesting that, in the patient dying of acute yellow atrophy in whom there was no attempt at repair, it was at about this time that clinical deterioration set in.

FATAL CASES

In the six fatal cases of our series the symptoms lasted from 11 days to 5 years. The liver in the case of the shortest duration showed acute yellow atrophy. Subacute necrosis, with multiple nodular hyperplasia, was the feature of cases of longer duration. The classical portal type of cirrhosis was not seen in this series (cf., Sherlock 1948).

Case 1.—A boy, aged $3^{1}/_{2}$ years, had an illness lasting 11 days, in which he was jaundiced and had malaise, vomiting, dark urine, and pale stools. On the ninth day he had intermittent bouts of abdominal pain and became comatose and restless, with exaggeration of tendon-reflexes and extensor plantar reflexes. His abdomen became grossly distended, and he had a hæmatemesis a few hours before death.

Necropsy.—The liver was much smaller than normal for the boy's age, and weighed 390 g. The cut surface had a yellowish-pink ground-glass appearance. Histologically there was acute hepatic necrosis without signs of nodular regeneration.

The patient's elder brother had had a bilious attack, with light stools and dark urine, $4^{1}/_{2}$ weeks before the onset of the patient's illness.

Case 2.—A boy, aged 7 years, had a history of vomiting and dark urine, 8 weeks before death, followed in a week by jaundice and pale stools but no loss of appetite. His liver was tender and reached four finger-breadths below the costal margin, and the tip of his spleen was palpable. His terminal state was characterised by vomiting, inability to see clearly, restlessness passing into coma, neck rigidity, ex plantar reflexes, sudden decrease in the size of the liver final hæmatemesis.

Necropsy.—The liver was small, with well-marked su liver atrophy, and there were multiple hæmorrhages lungs and mesentery.

Case 3.—A boy, aged 11 years, had an illness last weeks, starting with sickness and malaise, and succeed jaundice, after which he felt well in himself for a time, e for some epistaxes and muscular pains in the first fort of his illness. In the fourth week his abdomen became distended, with prominence of the superficial veins, marked ascites, and œdema of the abdominal wall and the liver and spleen could not be palpated. Parace was done four times, with removal of 54, 60, 200, and 2 The boy felt comfortable and ate well, but in the eighth of illness he became deeply jaundiced and his tempe rose gradually. There were no terminal cerebral signs.

Necropsy.—The liver weighed 720 g. and showed a irregular surface; on section there were irregular nodu olive-green tissue and microscopy showed multiple no hyperplasia, with terminal necrosis.

Case 4.—A boy, aged 10 years, had had an attack jaundice 10 weeks previously, with a rash resembling rub nausea, sickness for a week before the appearance of jaund dark urine, and pale stools. He had not been free f jaundice since but had improved and then relapsed. He bruising and petechiæ for a week and bleeding from g in the last 2 days. Liver and spleen were impalpable. T was terminal intracranial hæmorrhage. The serum-bilru level was 2 mg. per 100 ml.

Necropsy.—The liver weighed 1030 g., was moderat firm, and showed multiple nodular hyperplasia and subac necrosis.

Case 5.—A boy, aged $12^{1}/_{2}$ years, had had, at the age 7 years, an attack of jaundice which had lasted 17 we and been followed by recurrent attacks of abdominal pain jaundice and by profuse melæna on three occasions. liver had a hard edge, felt at the costal margin; his spleen grossly enlarged down to the level of the umbilicus; he had ascites and telangiectasia on his face and trunk. serum-bilirubin level was 10·4 mg. per 100 ml. He had termin epistaxis, melæna, spasticity of limbs, and coma.

Necropsy.—His liver weighed 1140 g. and was coars nodular, the nodules being bile-stained and the interven fibrotic tissue pink. His spleen weighed 1000 g. The li on section showed a late stage of subacute necros No varicosities were found; hæmorrhage was due hypoprothrombinæmia.

The next case is an example of multiple nodular hyp plasia with terminal necrosis, possibly following a s clinical hepatitis. It is included because the patholog findings were similar to those in the preceding cases.

Case 6.—A boy, aged 8 years, had been in good he up to July, 1948, when he developed abdominal pains, pall and temperature for a few days. Since then he had be unwell, lost half a stone in weight, and passed pale stoo on several occasions. He had had frequent epistaxes fo 12 months.

When first seen in September, 1948, he presented icter conjunctivæ; protuberant abdomen, with free fluid demo strable; liver firm and hard; liver and spleen both extendin three finger-breadths below the costal margin; and spid nævi on wrists, knees, and trunk. The serum-bilirubin lev was 3·7 mg. per 100 ml. Paracentesis abdominalis was required twice. A liver biopsy by laparotomy showed a tawny coloured hobnailed liver. Microscopically areas both o necrosis and of multiple nodular hyperplasia were present.

On Nov. 25, 1948, the jaundice greatly increased, the temperature rose to 103°F, œdema spread to sacrum and ankles, and the patient became drowsy, vomited altered blood, and died. The duration of the hepatic symptoms was 5 months or more but difficult to assess, because the onset was non-icteric.

This case closely resembles one of Cullinan's (1936), a boy, aged 12 years, who first had jaundice on the d before his death, but whose liver at necropsy showed cirrhosis and long-standing nodules.

The remaining six cases demonstrate in children three possible forms of sequelæ following infective hepatitis:

tients (51 alive and 40 dead) in whom the diagnosis sseminated sclerosis was confirmed were a biased le. For both series (the 91 cases used and the 54 followed up) information was available, with few tions, about sex, type of illness, and age at onset. stical comparisons were made between the two series ms of the distribution of each of these known facts, the results of these comparisons in no way suggest the differences between the used cases and the unused were greater than could easily have arisen by ce:

Sex-distribution: $\chi^2=0{\cdot}39$ D.F.=1 $0{\cdot}7>P>0{\cdot}5$.

Symptomatic distribution: $\chi^2=0{\cdot}13$ D.F.=1 $0{\cdot}8>P>0{\cdot}7$.

Distribution of monosymptomatic onsets as "motor" or al": $\chi^2=0{\cdot}17$ D.F.=1 $0{\cdot}9>P>0{\cdot}8$.

Age-at-onset distribution: $\chi^2=6{\cdot}93$ D.F.=5 $0{\cdot}3>P>0{\cdot}2$.

PROGNOSIS

e prognosis in disseminated sclerosis is generally idered to be uniformly bad, though Birley and geon (1921) and Heine (1936) state that the possi- y of a spontaneous cure cannot entirely be denied, Symonds (1948) has necropsy evidence of such a

> his patient died of pneumonia in her sixties. During he only evidence of a neurological condition was extensor ar reflexes. At necropsy scattered lesions of disseminated sis were found. Subsequent inquiry revealed that in her ties she had had fluctuating weakness of her legs, which tually improved, leaving her slightly lame but not venting her from leading an active life. There were no er symptoms of organic disease.

LE II—PROBABILITY OF SURVIVAL ACCORDING TO TYPE OF ONSET AND SEX

ars m et	Probability of surviving from onset to end of period shown					
	Males		Females		All cases	
	Mono-symptomatic	Poly-symptomatic	Mono-symptomatic	Poly-symptomatic	Mono-symptomatic	Poly-symptomatic
-4	0·91	0·89	1·00	0·88	0·95	0·89
5-9	0·84	0·76	0·91	0·76	0·87	0·76
-14	0·70	0·62	0·68	0·54	0·69	0·58
5-19	0·64	0·45	0·56	0·43	0·60	0·44
-24	0·26	0·30	0·56	0·29	0·34	0·29

rley and Dudgeon (1921) emphasised the better prognosis in the remittent type compared with the chronic ressive type of disseminated sclerosis. Brain (1936) shown that the acute extensive disease of young ts has a poor prognosis, the chronic spinal form of ddle age a better, and the remitting form the best gnosis. In cases with unilateral retrobulbar neuritis, in the absence of other symptoms and signs, it is sonable to hope that there will be a remission lasting ew, or possibly many, years. Similar observations were de by McIntyre and McIntyre (1943).

Symonds (1930) found that 28% of 139 patients had trobulbar neuritis as a *first symptom, and 15% as an* ly symptom. In 20 of these the next symptom veloped in less than two years, in 5 in less than five ars, and in 5 in more than five years.

Brown and Putnam (1939) have shown that symptoms e to small lesions, such as diplopia, central scotoma, d sensory disturbances of one extremity, tend to gress within a few months, whereas symptoms due to ge lesions, such as paraplegia, ataxia, and mental terioration, are usually permanent. First symptoms ve a higher rate of recovery than the same symptoms veloping later. Thysgesen (1947) states that the ognosis is unfavourable when optic-nerve symptoms pear early in the disease in association with other symptoms, and when disturbances of coördination appear in the initial stages.

TABLE III—TYPE OF ONSET ACCORDING TO AGE AT ONSET

Type of onset	Age at onset (yr.)										
	10–	15–	20–	25–	30–	35–	40–	45–	50–	Unknown	All ages
Monosymptomatic	2	5	10	10	9	10	8	—	—	2	56
Polysymptomatic	—	5	9	9	4	3	4	—	1	—	35
Total ..	2	10	19	19	13	13	12	—	1	2	91

The case-records of the 51 living and 40 dead patients of the present series were analysed. The onsets of the disease were divided into two categories: monosymptomatic and polysymptomatic. From a pathological point of view this is an artificial division, since it probably requires more plaques to produce symptoms in the long tracts, such as the pyramidal tracts, than in the short tracts, such as the optic nerves and posterior longitudinal bundles. Also it was difficult to be certain in what category some types of onset should be placed. Subjective symptoms, such as paræsthesiæ of the legs, where the lesion is in adjacent posterior columns, were labelled monosymptomatic, whereas weakness of both legs was called polysymptomatic because, both pyramidal tracts being involved, it required two plaques or more, or possibly one large plaque. Hence, as a rule, the case was labelled polysymptomatic when the symptoms were bilateral, except in the case of paræsthesiæ, and monosymptomatic when unilateral—e.g., in hemiparesis and monoparesis. An onset with weakness and paræsthesiæ of one limb was called monosymptomatic but was not included in the motor type of onset (see below).

Table I shows the sex-distribution of monosymptomatic and polysymptomatic onsets. Since 51 patients are still living, their ultimate prognosis is unknown. However, the living patients can be used in conjunction with the dead to give better estimates of survival-rates at certain periods after onset through which they have been exposed than could be obtained by use of the dead patients alone. The duration of the disease has been considered here in five-year periods and the technique used is set out in detail in the appendix.

From table II it will be seen that, except for males between 20 and 24 years from onset, the probability of survival is consistently less for the polysymptomatic group than for the monosymptomatic. Otherwise the figures for males and females are very similar. This is surprising, since in view of the effects of pregnancy on disseminated sclerosis, the prognosis would have been expected to be better in males. Four women in the series passed through pregnancies without adverse effect, including one who successfully weathered four pregnancies during a long remission. In 2 cases, however, the onset was precipitated by, or related to, childbirth.

Table III shows that the age of onset in the two groups, monosymptomatic and polysymptomatic, is somewhat different. Therefore the data have been divided into two groups according to the age (less than 25 and 25 or more) at onset, to see whether or not the differences in chance of survival are a function of age rather than of type of onset. Table IV shows that in each age-group the probability of survival up to 19 years after onset is consistently less for the patients with a polysymptomatic onset. Only in the patients aged up to 24 at onset is the probability of survival to 20–24 years from onset lower in the patients with a monosymptomatic onset and there were too few patients in this group for the findings to carry much conviction.

On the whole, then, the prognosis is less favourable for patients with polysymptomatic than with monosympto-

DI-ISOPROPYL FLUOROPHOSPHONATE AS AN INTESTINAL CARMINATIVE

G. C. Arneil M.D. Glasg.
A. S. Douglas M.B., B.Sc. Glasg., M.R.C.P.
From the Department of Materia Medica and Therapeutics, University of Glasgow, and Stobhill Hospital

In a clinical study of postoperative adynamic ileus Quilliam and Quilliam[1] commented favourably on di-isopropyl fluorophosphonate (D.F.P.), but they emphasised that it should be used only as part of the general management of such cases. The fact that the clinician is often obliged to adopt several different forms of treatment simultaneously obscures the part played by these measures individually. We have therefore investigated the carminative value of D.F.P. alone and in conjunction with posterior pituitary extract (P.P.E.). The D.F.P. was dispensed in arachis oil, and the dose was injected intramuscularly, equally divided between two sites to promote rapid absorption.

METHOD

The method of assessment used was that of Alstead and Patterson.[2] Observations were made on 23 patients. The intestinal gases were collected in a measuring cylinder with a rectal catheter. During a control period of two hours no drugs were given and nothing was taken by mouth. The patient then received his midday meal, and the postprandial output of flatus was noted. About two hours after the meal D.F.P. was injected intramuscularly, and the experiment was continued for a further two or three hours.

Twelve patients received D.F.P. alone, 3 of them receiving 2 mg. and the remainder 4 mg. Six patients received 4 mg. of D.F.P. and 3 units of P.P.E. simultaneously In addition 5 patients were given 4 mg. of D.F.P. followed by 2 units of P.P.E. thirty, sixty, and ninety minutes later, in order to maintain the effect of P.P.E. during the period of greatest activity of D.F.P.

RESULTS

A postprandial evacuation of gas was recorded in 13 of the 23 patients (56%). In 3 of the 12 patients given D.F.P. alone a smart carminative action was observed (450 ml., 330 ml., and 340 ml.). A smaller response was given by 3 other patients (180 ml., 105 ml., and 80 ml.). The response to D.F.P. was most striking in those patients who had already produced large postprandial evacuations of flatus. The action of D.F.P. was apparent in some cases a few minutes after administration and continued in others for at least two and a half hours. When D.F.P. and P.P.E. were given simultaneously, an early response occurred in 5 out of 6 patients and this was attributed to the action of the pressor principle in the P.P.E. A delayed action was explained by the relatively slow-acting D.F.P. and occurred in only 3 out of 6 patients. When small divided doses of P.P.E. were substituted for the single dose, 3 out of 5 patients showed a considerable response (150 ml., 280 ml., and 380 ml.), but it was no greater than the response of other patients to D.F.P. alone.

None of the 12 patients given D.F.P. alone showed any untoward effects. Of the 11 patients given D.F.P. and P.P.E., 2 developed severe reactions, with vomiting, colic, and frontal headache, and 3 other patients had similar but less severe symptoms. These troublesome side-effects occurred irrespective of whether the drugs were given together or spaced out as described above.

SUMMARY

Tested by its capacity to remove gas from the di-isopropyl fluorophosphonate was more or less in 12 out of 23 patients and produced no si

When this drug was given with posterior extract, no useful synergistic action occurred but effects were frequent and sometimes distressing.

We wish to thank Prof. Stanley Alstead for help advice in this work and Dr. A. D. Briggs, the medical tendent, for permission to publish the results. We indebted to Messrs. Allen & Hanburys Ltd., for of D.F.P.

DISSEMINATED SCLEROSIS

A FOLLOW-UP OF 91 CASES

J. H. D. Millar
M.D. Belf., M.R.C.P.
PRINCIPAL NEUROLOGICAL REGISTRAR, ROYAL VICTORIA HOSPITAL, BELFAST

The object of this follow-up was to discover the of patients in 1947 who had been diagnosed in 193 as having disseminated sclerosis. Most of them had investigated in hospital on at least one occasion. I tried to compare the prognosis of cases with types of onset and to consider familial aspects of disease and its possible association with the disease growing lambs known as swayback.

The material was drawn mainly from the re 137 patients examined in the Royal Victoria H Belfast, and of 25 in one consulting practice. W was found that there was great difficulty in tracing ma patients, 7 seen in other hospitals were included. Of the 169 patients, 121 were traced; 74 were alive and had died. Of the 74 alive, 6 either refused examinatio or could not be visited. Of the 68 examined, 51 confirmed as having disseminated sclerosis, 7 were uncertain diagnosis, and 10 were considered in 1947 be probably not cases of disseminated sclerosis. Of t 47 dead, after careful study of all available record including death certificates, 40 were considered to ha had disseminating sclerosis and 7 probably not. D seminated sclerosis was not mentioned in the dea certificates of 4 patients for whom the diagnosis was ver clear from the clinical records.

Of the 10 living patients who were probably n suffering from disseminated sclerosis 4 showed neith symptoms nor signs of any disease (they may possib have been enjoying long remissions), and 1 had angioma of the cervical cord (confirmed at operatio To the remaining 5 it was difficult to attach a satisfacto diagnosis: 1 of them showed definite signs of moto neurone disease of only a few years' duration, but seems unlikely that the symptoms on which disseminat sclerosis had been diagnosed could have any connexi with his present condition.

If the 54 patients who could not be followed up in 19 had disseminated sclerosis and were not available fo re-examination because they had died between 1937 an 1947, then the results of my investigation may b invalid. On the other hand, there is no evidence that th

TABLE I—SEX-DISTRIBUTION OF TYPES OF ONSET

Sex	Onset						Total		
	Monosymptomatic			Polysymptomatic					
	No. of patients								
	Alive	Dead	Total	Alive	Dead	Total	Alive	Dead	Total
Male ..	20	12	32	9	9	18	29	21	50
Female	15	9	24	7	10	17	22	19	41

CONTACT WITH SHEEP

w of recent work on swayback and its possible on with disseminated sclerosis, nearly all the interviewed were asked whether they had ever close contact with sheep or lambs. It had been plot the residence of the patients at the onset isease on a map showing the incidence of sway-Northern Ireland. The Ministry of Agriculture thern Ireland states, however, that there has evidence of swayback in the country, either r during this investigation. In 11 cases out of 49 s evidence of close contact with sheep or lambs ; compares with the incidence of the contact of eings with these animals in the general popula-nknown. One of the patients was working with Australia when his first symptoms came on.

SUMMARY

-one cases of disseminated sclerosis were to show the probability of survival at different after onset of the disease.

sults suggest that patients with a monosymp-onset have a better prognosis than those with a ptomatic onset ; patients with an onset with mptoms have a better prognosis than those with ymptoms ; and patients whose first symptoms efore they are 25 have a better prognosis than h a later onset.

out of eighty-nine families showed a disease like ated sclerosis in more than one member.

ack has so far not been reported among lambs ern Ireland. This is of interest in view of the ion by Coates (1930) that disseminated sclerosis nore common in this country than in other parts ritish Isles.

o thank the physicians of the Royal Victoria Hospital, or permission to use their cases ; Dr. R. S. Allison couragement, help, and stimulation ; Dr. J. Knowel-e London School of Hygiene and Tropical Medicine of the statistical work, and Dr. E. A. Cheeseman, partment of Social and Preventive Medicine, Queens y, Belfast, for the rest of the statistical work.

APPENDIX

Calculating Chances of Survival

ject is to compare the probabilities of survival of ps of patients at certain periods of duration of se—e.g., monosymptomatic with polysymptomatic one age of onset group with another, males with kc.

ta are available either as lengths of survival after 947 in the case of patients alive in 1947, or duration er onset in the case of patients who died before 1947. following explanation the data are grouped in five-ods after onset—i.e., 0–4, 5–9, 10–14, 15–19, and ars, indicated by the subscript 0, 1, 2, 3, and 4 ly, and in general by the subscript x.

presents the number of patients exposed in period x. he number of deaths in the same period, then :

of patients alive in 1947 and observed to the end of period x) $+ (d_x + d_{x+1} + d_{x+2} \dots .)$

hance of surviving period x is $1 - \frac{d_x}{P_x}$ or p_x.

x for each five-year period is an independent estimate ance of surviving period x based on the greatest f available data ; and the chance of surviving from the end of any given period, say t, is :

$$p_0 \times p_1 \times p_2 \times \dots \dots p_t$$

l Example

ulate the chance of survival from onset to 10 years—e end of the second period (data of males and females l with monosymptomatic onset) :

	Period 0–4 yr. (x=0)	*Period 5–9 yr.* (x=1)
atients alive in erred to end of	35	34
No. of deaths in period x and subsequent periods	$d_0 + d_1 + d_2 + d_3 + d_4 = 21$	$d_1 + d_2 + d_3 + d_4 = 18$
No. of patients exposed in period x	$P_0 = 35 + 21 = 56$	$P_1 = 34 + 18 = 52$
No. of deaths in period x	$d_0 = 3$	$d_1 = 4$
Chance of surviving period x	$\left(1 - \frac{d_0}{P_0}\right) = \left(1 - \frac{3}{56}\right) = 0{\cdot}95$	$\left(1 - \frac{d_1}{P_1}\right) = \left(1 - \frac{4}{52}\right) = 0{\cdot}92$

∴ Chance of surviving from onset to end of second period—i.e., 10 years after onset—is $p_0 \times p_1 = 0{\cdot}95 \times 0{\cdot}92 = 0{\cdot}87$.

EXPERIMENTAL TYPHOID INFECTION TREATED WITH CHLOROMYCETIN AND SULPHADIAZINE

A. W. El Borolossy
M.B. Cairo, Ph.D. Lond.

G. A. H. Buttle
O.B.E., M.A. Camb., M.R.C.S.

From the Department of Pharmacology, School of Pharmacy, University of London

Preliminary reports on the treatment of typhoid fever with chloromycetin indicate that this drug usually causes rapid subsidence of fever and a corresponding symptomatic improvement (Woodward et al. 1948, Murgatroyd 1949, Bradley 1949) ; but treatment has to be continued for at least 8 days, and the relapse-rate is high. El Ramli (1949) has found that of 17 patients treated with chloromycetin 9 (53%) relapsed, compared with 16 (13%) of 122 untreated controls ; he has also found that, in the doses used, chloromycetin gave rise to some toxic manifestations, of which the commonest were anorexia, stomatitis, glossitis, skin rashes, and mental apathy.

A synergistic action between penicillin and sulphonamide compounds on *Salmonella typhi* was first reported by Bigger (1946), and advantage has been taken of this phenomenon in treating typhoid fever (Comerford et al.

TABLE I—AVERAGE SURVIVAL PERIODS IN DIFFERENT GROUPS OF MICE TREATED WITH CHLOROMYCETIN BY VARIOUS DOSAGE SCHEMES

Chloromycetin, dose (mg.)	Dose given at time of infection		Dose given three times at 3-hourly intervals	
	No. of mice	Average survival period (days) after death of all controls	No. of mice	Average survival period (days) after death of all controls

4	18	2·7	12	6·4
2	12	2·0	12	4·5
1	12	0·25	12	1·4
0	36	..	18	..

matic onsets. It must be emphasised that, though the results of statistical analysis are uniformly suggestive in this respect, no significant differences were obtained in this small series. However, in general the findings agree with clinical impressions. One finding not in general agreement with clinical impression is that patients whose symptoms appear before the age of 25 have a better prognosis that those with a later onset. But some of the older patients may have forgotten a symptom earlier in life which would either have placed them in the younger category or given better figures for their own group.

Müller (1949), who investigated the symptomatology, course, and prognosis in 810 cases, found that the probability of surviving different five-year periods after the onset was greater in each successive period. He too showed that an onset after the age of 25 years carried a worse prognosis than under 25, and that there was little to choose in outlook where the sex of the patient was concerned. He calculated that the average duration of illness for disseminated sclerosis lay between 16 and 34 years.

In table v the monosymptomatic patients have been divided into two groups; 19 with a visual onset (amblyopia and diplopia), and 17 with a motor onset (weakness of a hemiplegic distribution or weakness of an arm or leg without subjective sensory symptoms). Since there was little difference in sex and age distribution between the groups they have not been further divided. The "visual" group have better probabilities of survival than the "motor" group, and the differences between "visual" and "motor" at any period are greater than the corresponding differences between monosymptomatic and polysymptomatic groups. This might be expected from clinical experience, but the comparison is not entirely justifiable, since it probably requires several lesions at different levels to interrupt functional motor activity, whereas a solitary lesion in the optic nerve will cause transient impairment of vision. Müller (1949) showed that in his large series the prognosis was more favourable for sensory and cranial-nerve disturbances than for motor and sphincter disorders. Also, when motor disorders were an initial symptom there was a greater likelihood that the disease would be progressive, and this risk was greater with increasing age.

TABLE IV—PROBABILITY OF SURVIVAL ACCORDING TO AGE AT ONSET

Years from onset	Probability of surviving from onset to end of period shown			
	Onset at 0–24 yr.		Onset at 25 or more yr.	
	Mono-symptomatic	Poly-symptomatic	Mono-symptomatic	Poly-symptomatic
0–4	1·00	0·93	0·92	0·86
5–9	0·94	0·79	0·84	0·75
10–14	0·80	0·71	0·65	0·48
15–19	0·71	0·62	0·55	0·24
20–24	0·35	0·50	0·55	0·00

FAMILIAL INCIDENCE

Disseminated sclerosis can be closely simulated by many familial diseases of the central nervous system, such as familial ataxias (Hall and Mackay 1937), Schilder's disease (Ferraro 1927, Symonds 1928), hereditary cerebellar disease of Marie, Pelizæus Merzbacher's disease, and others (Ferguson and Critchley 1929). Certainty can only be established by necropsy.

Published reports were found of nine families in which more than one member had disseminated sclerosis verified by necropsy: Ellermann (1935) collected reports of six such families and reported one of his own; and Maier (1947) reported necropsy findings of diss sclerosis in a mother, her son, and her daughter. and Keschner (1943) added a brother and sister necropsy confirmed the diagnosis in one case. Ho in view of the paucity of confirmation by nec the published reports, most writers agree that f disseminated sclerosis is the result more proba chance or a common source of infection than of influences. This attitude is supported by work on Curtius (1933) calculated that there should be 370 with disseminated sclerosis in Germany. Thums (found thirteen pairs of identical twins of whom twin had disseminated sclerosis but the other had he concluded that there was no hereditary in disseminated sclerosis. Twins suffering from di sclerosis, without pathological confirmation, have reported by Legras (1934), Astwazaturow (1935), Williams (1946).

TABLE V—PROBABILITY OF SURVIVAL IN ALL MONOS PATIENTS ACCORDING TO WHETHER THE FIRST WAS MOTOR OR VISUAL

Years from onset	Probability of surviving from onset to end of period shown	
	Motor onset	Visual
0–4	0·94	1·00
5–9	0·78	0·95
10–14	0·57	0·82
15–19	0·45	0·75
20–24	0·00	0·45

In the present series 3 families out of 89 show probable familial incidence:

Case 1.—A male farm labourer, aged 28, with a prog illness which, despite the absence of remissions, cou regarded as disseminated sclerosis, had had a sister who died in a mental hospital at the age of 35 and had been nosed as a "typical case of disseminated sclerosis." She been emotionally unstable, with staccato speech, sp paraplegia, worse in one leg, and absence of abdo reflexes. The colloidal gold reaction of her cerebro fluid had shown a paretic curve associated with a neg Wassermann reaction. There were nine other siblings and healthy, none with any deformity suggesting a fam disease.

Case 2.—A plumber, aged 32, also had a of disseminated sclerosis, but he had a history of retrobulbar neuritis which had lasted a month in year of his illness. His sister, a housewife aged 40, had ness of the legs without any remissions but could be to have disseminated sclerosis. She had a according to her doctor, also seemed to have sclerosis. This daughter had complained in June, paræsthesiæ of the left leg, and had had no abnormal phy signs, except that the knee-jerks had been brisk and plantar reflexes were possibly extensor. Three months the paræsthesiæ had cleared, but she had complaine weakness of the left leg. The plantar reflexes on this occ had been definitely extensor. A few days later she had plained of paræsthesiæ of the fingers. In October, 1946 had had pain in the distribution of the first and se divisions of the left trigeminal nerve and "irritations the left eye. Examination had shown hyperalgesia in distribution, and the plantar reflexes had remained exte A year later all symptoms had cleared, with the pl reflexes still extensor.

Case 3.—A woman, aged 37, had had weakness of the ri leg as the initial symptom, which had varied from time time. This had been followed three years later by trans paræsthesiæ. Her brother, aged 26, had had a more typ history, with initial urinary symptoms leading to retention of urine, followed by weakness and ataxia of the and a recent history of blurring of vision. He had hæmatemesis in 1933. There were nine siblings in the three having had operations for duodenal ulcers, but the six being healthy. Both parents were healthy and li and 82 years.

sputum. No pathogens were isolated from the fæces :.

lay 13 the temperature was normal and the pulse-rate nin. On the 20th the patient felt well and was able to On the 31st he was transferred to a convalescent Two days later he was readmitted to hospital with and abdominal pain of sudden onset. On June 6 e from enteric fever was provisionally diagnosed.

une 13 we were asked to see him from a surgical point . He was then having an exacerbation of central nal pain, and a watery stool was being passed every so. He was dehydrated. His pulse-rate was 88 per nd temperature 100·8°F. His abdomen appeared distended. There was a well-localised and limited acute tenderness 2 in. below and to the right of the us. The local muscle guarding present did not seem to mensurate with the acute tenderness. Occasional but aggerated bowel sounds could be heard. The spleen palpable, and there was no diminution of liver dullness. examination produced discomfort bordering on tender- ut no mass was felt.

a this clinical picture it was inferred that there probably intense inflammatory condition limited to a segment lower ileum. Since a mass was not felt, it was thought ere could be little induration of the bowel wall and no tal tumour." Perforation was considered, particularly of the provisional diagnosis of enteric fever. A straight the diaphragmatic areas was therefore arranged for llowing morning. Intravenous replacement of fluids lectrolytes was begun, and intramuscular penicillin ccinyl sulphathiazole by mouth were given.

t morning, June 14, the patient's general condition ghtly improved. Physical signs in the abdomen were nged, but the diarrhœa had ceased and the abdominal vas less frequent. The straight film of the abdomen d gas under the diaphragm on both sides. This incon- tible evidence of a perforation of the alimentary tract the question of laparotomy a matter for urgent con- tion. However, all the signs and symptoms pointed to rforation being probably pin-point (allowing the escape but not of fæces) and now well localised. Conservative ent was therefore continued under careful observation. llin 20,000 units three-hourly and succinyl sulpha- le 3 g. four-hourly were given. One pint of fresh blood ransfused intravenously, and this was followed by 5% e in physiological saline. On the 16th the patient was improved, and the intravenous infusion was stopped. 17th *S. typhi* was isolated from the fæces. On the 25th tient was still making excellent progress. There were no ninal symptoms or signs, and the temperature and pulse normal. A few weeks later he made a complete recovery as transferred to a convalescent home.

wish to thank the Director-General of Army Medical es for permission to publish.

ION OF SODA LIME ON CHLOROFORM

H. LLEWELLYN BASSETT

M.A. Camb., B.Sc. Lond.

RER IN ORGANIC CHEMISTRY, UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE

HEN chloroform is brought into contact with alkali, may be, according to the conditions, one of three ts:

No appreciable reaction.

Decomposition of the chloroform into sodium formate:

$$CHCl_3 + 4\,NaOH = 3\,NaCl + H.COONa + 2H_2O$$

Decomposition of the chloroform into sodium chloride carbon monoxide:

$$CHCl_3 + 3\,NaOH = 3\,NaCl + CO + 2H_2O$$

as also been stated,[1] apparently on the basis of a le experiment, that sodium chloride and phosgene formed when a mixture of chloroform vapour and s passed over solid alkali:

$$CHCl_3 + NaOH + O = NaCl + COCl_2 + H_2O$$

here seems to have been little investigation into t may happen when a mixture of chloroform vapour oxygen is passed through soda lime under the condi- s obtaining when chloroform is used as an anæsthetic in a closed circuit. At the suggestion of Dr. William W. Mushin, director of the department of anæsthetics in the Welsh National School of Medicine, I have made several experiments, the results of which are summarised below.

There are substantial reasons for doubting the statement[1] that phosgene may be produced, and in one series of experiments mixtures of chloroform vapour, and oxygen, with and without carbon dioxide and air, were passed through soda lime under very varied conditions. A careful search did not reveal the slightest trace of phosgene.

Though the decomposition of chloroform by alkali is usually represented by equation (2), early though neglected work[1,2] shows beyond question that under appropriate conditions the reaction may chiefly follow the course represented in equation (3). In some experiments more than 90% of the chloroform was converted into carbon monoxide, but very small variations in conditions can alter the course of the reaction to a surprising extent and rather erratically.

RESULTS

In the present experiments it was found that, when mixtures of 2 or 5% chloroform vapour in oxygen were passed through moistened soda lime at 50°C at a rate of 2 or 3 litres a minute—i.e., considerably slower than the mean breathing-rate—about 1% of the chloroform was converted into carbon monoxide at each passage, though there was considerable variation with the rate of flow. Very little formate was produced. No carbon monoxide could be detected when the gas mixture passed rapidly.

Experiment confirmed that the hydrochloric acid and any formic acid produced by the destruction of chloroform under these conditions are completely trapped by the soda lime; hence it is possible to find, with certainty, the amount of decomposition in a given instance by estimating the chloride left in the soda lime at the end of the operation, allowing for any chloride originally present. Moreover, if there had been any material decomposition, an estimation of formate will give, by difference, the quantity of carbon monoxide actually produced.

Dr. Mushin has kindly provided me with three used charges of soda lime from cases where chloroform had been administered as an anæsthetic. The chloride content of all three showed that there had been only very slight decomposition of the chloroform used. The amount of formate in any one charge was too small for a reliable estimation, but the result showed that, even if all the chloroform destroyed had been converted into carbon monoxide, in the worst case some 16 c.cm. of this gas would have been produced over the whole period of the anæsthesia.

SUMMARY

Experiments were conducted to study the action of soda lime on chloroform.

Under the conditions obtaining in a closed-circuit apparatus during the production of anæsthesia little decomposition takes place.

Three specimens of soda lime from clinical cases were examined. No more than 16 c.cm. of carbon monoxide could have been produced in any one case.

1946, 1947, McSweeney 1946, El Ramli and El Borolossy). This synergism is evident with experimental infections in mice (El Borolossy and Buttle 1949); and the present study, also in mice, was undertaken in order to find out whether similar synergism existed between chloromycetin and the sulphonamides.

The protective action of different doses of chloromycetin in *Salmonella typhi* infection in mice was first investigated.

METHOD

White mice with an average weight of 20 g. were infected with the Rawling strain of *S. typhi* (from the Wellcome Foundation) by intraperitoneal injection of 5×10^8 organisms (10,000 times L.D. 50), suspended in 0·5 ml. of 5% mucin. The drugs were given by mouth suspended in mucilage of tragacanth. In each experiment a control group of infected animals left without treatment all died within twenty-four hours. The number of survivors in each treated group was recorded daily up to seven days. The comparative value of the different forms of treatment was estimated by comparing the average survival periods of the mice in each group, obtained by adding together the number of days survived by each mouse and dividing the sum by the number of mice in the group.

RESULTS

The maximum tolerated dose of chloromycetin in mice is said to be 200 mg. per kg. body-weight (Smith et al. 1948). In our experiments, however, 20 g. mice tolerated a dose of 8 mg.—i.e., 400 mg. per kg. Smith and his colleagues found that chloromycetin is rapidly excreted by mice; and this may mean that the therapeutic response would be better with repeated doses during the first twelve hours following infection than with a single dose at the time of infection. Table I shows clearly that repetition of the treatment increases the survival period.

The effect of sulphadiazine and chloromycetin together was then studied; 8 mg. of sulphadiazine was given with 4, 2, or 1 mg. of chloromycetin, and the average survival period was compared with that after giving chloromycetin alone (table II).

COMMENT

From table II it is evident that sulphadiazine and chloromycetin exerted a synergistic action against *S. typhi* infection; their combined use increased the average survival period by 2·2, 2·6, and 12·8 times when 4, 2, and 1 mg. of chloromycetin was used. A significant correlation between the doses of chloromycetin and the resulting effect has been found, and the regression line was calculated. The doses of mycetin which would produce average survival of 6·0, 5·2, and 3·2 days were then calculated; periods, as will be noted, correspond to the effect of 4, 2, and 1 mg. of chloromycetin when combined with 8 mg. of sulphadiazine (tabl

TABLE III—DOSES OF CHLOROMYCETIN REQUIRED TO PRODUCE AN EQUIVALENT THERAPEUTIC EFFECT WHEN GIVEN ALONE AND WHEN GIVEN WITH SULPHADIAZINE

Average survival period (days) after death of all controls	Chloromycetin, effective dose (mg.)	
	Given alone	Given with 8 mg. sulphadiazine
6·0	6·83	4
5·2	6·14	2
3·2	4·4	1

Table III shows that the effect produced by a dose of chloromycetin *can be obtained by a fr* that dose combined with sulphadiazine; but this sulphadiazine by itself has no appreciable effect.

This phenomenon may prove of clinical value, the following advantages: (1) conservation of mycetin, which is still scarce and expensive in (2) lessened risk of toxic reactions; and (3) *diminution of the high relapse-rate observed in* treated with this drug.

Sulphathiazole is probably preferable to su for use in the human cases.

SUMMARY

The therapeutic effect of chloromycetin in S. infection in mice has been studied.

A synergistic action between chloromyceti sulphadiazine against this infection has been

Possibly treatment with chloromycetin and thiazole together may give satisfactory results in fever.

This work has been undertaken with the grant from the Medical Research Council, made to (G. A. H. B.).

r sputum. No pathogens were isolated from the fæces e

lay 13 the temperature was normal and the pulse rate min. On the 20th the patient felt well and was able to . On the 31st he was transferred to a convalescent Two days later he was readmitted to hospital with and abdominal pain of sudden onset. On June 6 so from enteric fever was provisionally diagnosed

une 13 we were asked to see him from a surgical point r. He was then having an exacerbation of central nal pain, and a watery stool was being passed every r so. He was dehydrated. His pulse rate was 88 per nd temperature 100.8 F. His abdomen appeared distended. There was a well-localised and limited acute tenderness 2 in. below and to the right of the us. The local muscle guarding present did not seem to mensurate with the acute tenderness. Occasional but aggerated bowel sounds could be heard. The spleen palpable, and there was no diminution of liver dullness. examination produced discomfort bordering on tender- st no mass was felt.

n this clinical picture it was inferred that there probably intense inflammatory condition limited to a segment lower ileum Since a mass was not felt, it was thought re could be little induration of the bowel wall and no tal tumour." Perforation was considered, particularly of the provisional diagnosis of enteric fever. A straight the diaphragmatic areas was therefore arranged for lowing morning. Intravenous replacement of fluids ectrolytes was begun, and intramuscular penicillin ccinyl sulphathiazole by mouth were given.

morning, June 14, the patient's general condition ghtly improved. Physical signs in the abdomen were nged, but the diarrhœa had ceased and the abdominal was less frequent. The straight film of the abdomen d gas under the diaphragm on both sides. This incon ble evidence of a perforation of the alimentary tract the question of laparotomy a matter for urgent con- tion. However, all the signs and symptoms pointed to foration being probably pin point (allowing the escape but not of fæces) and now well localised Conservative nt was therefore continued under careful observation in 20,000 units three-hourly and succinyl sulpha- le 3 g. four-hourly were given. One pint of fresh blood ransfused intravenously, and this was followed by 5% e in physiological saline. On the 16th the patient was improved, and the intravenous infusion was stopped. 17th *S. typhi* was isolated from the fæces. On the 25th ent was still making excellent progress. There were no minal symptoms or signs, and the temperature and pulse normal. A few weeks later he made a complete recovery as transferred to a convalescent home.

ION OF SODA LIME ON CHLOROFORM

H. LLEWELLYN BASSETT
M.A. Camb., B Sc Lond.
TER IN ORGANIC CHEMISTRY, UNIVERSITY COLLEGE OF
SOUTH WALES AND MONMOUTHSHIRE

HEN chloroform is brought into contact with alkali, may be, according to the conditions, one of three ts:

No appreciable reaction.

Decomposition of the chloroform into sodium formate:

$$CHCl_3 + 4\,NaOH = 3\,NaCl + H\,COONa + 2H_2O$$

Decomposition of the chloroform into sodium chloride carbon monoxide:

$$CHCl_3 + 3\,NaOH = 3\,NaCl + CO + 2H_2O$$

as also been stated,[1] apparently on the basis of a le experiment, that sodium chloride and phosgene formed when a mixture of chloroform vapour and s passed over solid alkali:

$$CHCl_3 + NaOH + O = NaCl + COCl_2 + H_2O$$

here seems to have been little investigation into t may happen when a mixture of chloroform vapour oxygen is passed through soda lime under the condi- obtaining when chloroform is used as an anæsthetic in a closed circuit. At the suggestion of Dr. William W. Mushin, director of the department of anæsthetics in the Welsh National School of Medicine, I have made several experiments, the results of which are summarised below.

There are substantial reasons for doubting the statement[1] that phosgene may be produced, and in one series of experiments mixtures of chloroform vapour and oxygen, with and without carbon dioxide and air, were passed through soda lime under very varied conditions. A careful search did not reveal the slightest trace of phosgene.

Though the decomposition of chloroform by alkali is usually represented by equation (2), early though neglected work[1,2] shows beyond question that under appropriate conditions the reaction may chiefly follow the course represented in equation (3). In some experiments more than 90% of the chloroform was converted into carbon monoxide, but very small variations in conditions can alter the course of the reaction to a surprising extent and rather erratically.

RESULTS

In the present experiments it was found that, when mixtures of 2 or 5% chloroform vapour in oxygen were passed through moistened soda lime at 50°C at a rate of 2 or 3 litres a minute—i.e., considerably slower than the mean breathing-rate—about 1% of the chloroform was converted into carbon monoxide at each passage, though there was considerable variation with the rate of flow. Very little formate was produced. No carbon monoxide could be detected when the gas mixture passed rapidly.

Experiment confirmed that the hydrochloric acid and any formic acid produced by the destruction of chloroform under these conditions are completely trapped by the soda lime; hence it is possible to find, with certainty, the amount of decomposition in a given instance by estimating the chloride left in the soda lime at the end of the operation, allowing for any chloride originally present. Moreover, if there had been any material decomposition, an estimation of formate will give, by difference, the quantity of carbon monoxide actually produced.

Dr. Mushin has kindly provided me with three used charges of soda lime from cases where chloroform had been administered as an anæsthetic. The chloride content of all three showed that there had been only very slight decomposition of the chloroform used. The amount of formate in any one charge was too small for a reliable estimation, but the result showed that, even if all the chloroform destroyed had been converted into carbon monoxide, in the worst case some 16 c.cm. of this gas would have been produced over the whole period of the anæsthesia.

SUMMARY

Experiments were conducted to study the action of soda lime on chloroform.

Under the conditions obtaining in a closed-circuit apparatus during the production of anæsthesia little decomposition takes place.

Three specimens of soda lime from clinical cases were examined. No more than 16 c.cm. of carbon monoxide could have been produced in any one case.

. . . Man is *not* a social animal who has, in some mysterious way, contracted a disease of selfishness, of sloth, and evil sexual desires. These are not due to Satan, Original Sin, Karma, or some incredible rebellion of man against his Maker, they are simply inherited instincts derived from his forbears. . . . We have only to make one great yet simple change—assert that man's original state was that of the *non social hunter*—and all the facts about man marshal themselves afresh, re orientate themselves, and fit into their true position"—ALFRED MACHIN in *What is Man?* London: C. A. Watts, 1949.

Medical Societies

ROYAL SOCIETY OF MEDICINE

The Section of Psychiatry's Symposium

FROM A CORRESPONDENT

PSYCHIATRY of the major psychoses, until fifteen years ago one of the least therapeutically minded branches of medicine, has lately burst out into an afflorescence of physical treatments, some of them purely empirical and without adequate rationale. The trend has been taken up with much vigour in this country by many specialists including neurosurgeons, not always with the necessary discrimination. It was therefore both instructive and corrective to listen to a group of experts from the U.S.A. who, on their way home from the International Neurological Congress in Paris, took part on Sept. 12 and 13 in a two days' symposium arranged by the section of psychiatry of the Royal Society of Medicine.

The meeting opened with four papers on recent advances in the surgical treatment of mental illness originally based on the operation of prefrontal leucotomy introduced by Moniz. The developments described were designed either to avoid the uncertainties of prefrontal leucotomy as to localisation of the cut, or to obviate its undesirable side-effects, or both.

Prof. **LARRY POOL** was the first to replace the "blind" method of cutting the fibres leading from the frontal lobe to lower centres, by systematic removal of frontal areas, which he calls topectomy.[1] The disadvantage of his method is the need for careful control of the blood-supply of the removed area, which may involve larger parts than was originally intended.[2]

Dr. W. B. **SCOVILLE** tries to avoid this by his method of selective cortical under-cutting in which the areas are separated from the underlying white matter without being removed. From his description and illustrations it was obvious that the technique requires a smaller operational field than topectomy and can be performed with greater speed and with minimal damage to the adjacent tissue. His most striking finding was the lack of specificity of function of the different frontal areas he isolated. The results were similar from under-cutting the medial or orbital areas or the convexity, but were related to the quantity of tissue involved. This observation tallies with Alfred Meyer's observation that the effect of leucotomy depends on the amount of fibres cut. So far Scoville has operated on over one hundred cases and the clinical results are similar to those of the standard operation with, however, better preservation of the patient's personality.

The procedures of Pool and Scoville require a neurosurgeon and a surgical organisation that seldom exists in mental hospitals; but Prof. **WALTER FREEMAN** claimed good results in milder cases for his transorbital lobotomy. To his original technique[3] he has now added a special twist of the instrument making the operation more effective.

Freeman was the first to show that successful severing of the frontal white matter is followed by degenerations in the dorsomedial nucleus of the thalamus. This has led Prof. E. **SPIEGEL** and Dr. H. T. **WYCIS** to their operation of thalamotomy. Dr. Wycis described how, by an adaptation of the Horsley-Clarke stereotaxic technique, he and his colleagues have succeeded in producing lesions in this nucleus. With the aid of a colour film he gave an impressive demonstration of the care taken to localise the lesion effected by electrical coagulation, and to obtain a predicted result without causing any cortical damage. Dr. Wycis dealt with the technique of the operation, while Prof. Spiegel reported on the physiological and psychological results. Immediately after the operation the patient is somnolent and apathetic and suffers from memory defect. These symptoms are, however, transitory. The final effect of the operation is similar to that of prefrontal leuco there being reduction of fear, anxiety, and tension some loss of initiative. Rorschach tests carrie before and after the operation showed little c indicating that the patient's basic personalit unaffected; no change in intelligence was found. series of 59 cases there had been 2 deaths; und side-effects had been transient and included slight of one leg, and in one patient some hyperæsthesia arm, which disappeared in a few weeks. This int procedure, which has to be controlled by re X rays, promises important neurophysiological o tions, some of which were reported by the speak

From the point of view of the clinician Dr. **HOCH** pointed out that while the results of pre leucotomy had shown that no specific functio localised in the various areas of the prefrontal c there was no doubt that the operations obtain som more than non-specific brain damage. He studi effect of leucotomy in patients with non-psy personalities where the operation had been perf for the relief of persistent and intolerable pain. In gence is unaltered, but creativeness, foresight, planning ability are impaired and there is a ce apathy and lack of drive and initiative. In psyc patients the basic structure of the psychosis rem unchanged, but the patient's attitude towards symptoms has altered.

As regards the problem of what type of leucotom indicated in different clinical syndromes, little is as known. Transorbital leucotomy, since it involves least change in personality, is, according to H theoretically the operation of choice for early case schizophrenia, for affective psychoses, and for obsessi neurosis. With schizophrenia of longer standing a m extensive operation is required; and topectomy, cor under-cutting, or a standard leucotomy should carried out—the last particularly if aggression i prominent symptom.

Prof. W. **FREEMAN** felt that most leucotomies unnecessarily extensive. The extent of frontal-l isolation must be balanced against the fact that superficial a cut may be ineffective in the relief symptoms.

Dr. C. C. **BURLINGAME** described an elaborate rehab tation programme after leucotomy. As a result of operation the patient's personality becomes m malleable. Dr. Burlingame disapproves of the patie returning to the chronic psychotic ward and equally his premature discharge from hospital. Ideally, p leucotomy cases should at first be treated in a spe group because they tend to antagonise other convale patients and to interfere with their recovery. personal relations, vocational training, and proper u leisure-time deserve full attention especially in pa who have spent many years in hospital before operation.

Dr. L. **KALINOWSKY**, who first introduced the n generally applied method of electrically induced c vulsions into this country and the U.S.A., compared t procedure and insulin treatment with the operative te niques. His attitude is conservative; he prefers the l drastic treatments, resorting to neurosurgery only wh these have failed. In his experience, cases of schi phrenia with predominantly neurotic symptoms a paranoid cases of late onset which resist insulin therap respond well to leucotomy, as also do patients sufferi from involutional melancholia with bizarre soma delusions not responding to convulsant therapy. Oth indications for leucotomy—preferably by one of t modified techniques—are certain cases of affect psychoses where electrical convulsive therapy has pe sistently failed and cases of severe chronic neuroses of t obsessional type. He has found the results of leucotom in psychopathic states disappointing. In Kalinowsky view, insulin and convulsant therapies exert a dire effect on the psychosis. Patients with good prognos improve early in the course of treatment, and if recove takes place it does so with good insight; relapse however, are common. After leucotomy the type improvement is different in kind. Insight remains poo

Control of hypertension in advancing years

'THEOGARDENAL' brand

theobromine and phenobarbitone tablets

Combining the cardiac stimulant action of theobromine with the sedative effect of phenobarbitone, 'Theogardenal' is of particular value in alleviating the symptoms of hypertension, and especially in lessening the distressing effects of cerebral vascular changes. Middle-aged and elderly patients experience marked relief from giddiness, headache, loss of memory, and insomnia. The drug has no cumulative effect and is well tolerated over lengthy periods.

Containers of 25, 100 and 500 tablets
(Each tablet contains theobromine gr. 5 and phenobarbitone gr. ¼)

Our Medical Information Division will be pleased to send a copy of the medical booklet 'M&B Barbiturates in General Practice' on request

More—or less—meat? While the hopes of Britons fall and rise with the ration—as its value changes from 1/2d. to 10d., to 1/1d., to 1/4d.—must their nourishment fluctuate, too? This question looms large in many minds.

Well, an ounce of beef contains about 4.5 grammes of protein—that essential nutrient. So every extra ounce of meat provides *that* much extra protein, and every ounce lopped off the ration deprives us of *that* much vitally needed food.

If meat were our only source of protein, this fluctuating ration *could* be serious. But it's fortunate that there are other just as useful foods, and correct nutritional technique at the moment is to rely on them for protein, accepting the meat ration, whatever its size, as a weekly treat! The "other foods", of course, being milk, cheese, eggs, fish . . . . *and Bemax.*

For patients requiring a generous protein intake, Bemax will be found an invaluable supplementary food. Its protein content is higher than that of most other common foods, and amino-acid analysis shows its protein to be more like that of 'animal' than 'vegetable' origin. Actually, weight for weight, Bemax supplies *more* protein than does lean beef, and comparison of essential amino-acid contents shows it to be of *equal protein value* with beef.

The recommended daily ounce of Bemax supplies in a week more protein than the meat ration (taken as steak). ***This in addition to its well-known vitamin contents!***

VITAMINS LTD., UPPER MALL, LONDON, W.6.

a loop. The vectogram is the projection of the loop on to a plane. The vectogram shows by the direction of the loop the mean direction of the propagation of the cardiac impulse, and by its length the total electromotive force of the impulse from moment to moment. The cathode-ray oscillograph allows these records to be made easily. The photographic record is traced and enlarged. The authors have devised an ingenious method of making wire models of the loops in three dimensions. The whole process takes about five hours.

The first section of the book deals with the physiological bases and physical aspects of the study. In a later section the authors have calculated the standard bipolar and unipolar curves which might be derived from the vectograms and compared them with those obtained with the cardiograph. The results seem to show a satisfactory correlation. As regards the unipolar precordial leads they have compared the calculated curves obtained from a vectogram in the horizontal plane with the actual curves obtained, again with a good agreement. A number of examples of the commoner types of pathological curves are shown in another section.

Duchosal and Sulzer conclude that vectocardiography has a practical value. While it is true that there is a very wide range of abnormal loops, there is only one lead, as it were—in contrast to the considerable number now in use in ordinary cardiography. Once the principles are mastered the new method may prove to be the simpler and more inclusive. This book is not easily grasped, and the study of the subject is novel and hard. But it deserves attention, and the book should be widely read, though the mathematical part will be beyond the range of many. The illustrations and the explanations are good and clear.

Advances in Surgery

Editor: WILLIAM DE WITT ANDRAS. New York: Interscience Publishers. 1949. Pp. 554. 66*s*.

THIS first volume strikes a new note in publications for the surgeon eager to keep abreast of his subject. It is by no means a résumé of recently published papers, for it contains only seven contributions. Each of these, however, deals with a subject of great importance, bristling with unsolved problems. In every case the author is an acknowledged master in the field in which he writes. It is doubtful whether anywhere so many relevant facts about shock could be found collected together and commented upon with such judgment as in Jacob Fine's article. But almost the same praise could be given to all the contributions. Strictures of the common bile-duct, the regeneration of nerves, the problems of the immersion-foot syndrome, vessel anastomosis for portal obstruction, bone tumours, and antibiotics are all in the forefront of surgery and are all discussed in the light of new knowledge. This series may not have a wide public, but it will certainly be popular among surgeons of enterprise, imagination, and vision.

Das Hungerödem und andere alimentäre Mangelerkrankungen

Prof. HANS W. BANSI, senior physician, 1st medical department, St. George's Hospital, Hamburg. Stuttgart: Enke. 1949. Pp. 211. DM. 22.80.

ALTHOUGH a great deal of propaganda was put out to magnify its severity, the undernutrition in Germany between 1945 and 1948 was never very serious. Morals became lax but civilisation never broke down, and there was never anything comparable with the famines which decimated the concentration camps in Germany during the war.

This book is based on observations of moderate undernutrition at Hamburg, and the approach is largely clinical. Its main title, "Das Hungerödem," is misleading, for its subject is undernutrition generally, and the author devotes a good deal of space to his so-called "Mangelfettsucht" or "Paradoxe Fettsucht"—a syndrome consisting in excessive fatness in repatriated prisoners-of-war and in young women who have never left Germany. Some of the latter are described as having amenorrhœa, and the author thinks that some endocrine disturbance was responsible. The book contains some quantitative data about serum-proteins and dietary value of particular amino-acids, and of fish, and other kinds of protein in convalescence it also includes a great deal of somewhat information about essential amino-acids, carbohydrate metabolism, and so on. It is German in its approach and treatment of the matter, with neither the critical outlook nor the expected in other countries today; but it contains valuable information and there is a good index enables the reader to find this fairly easily.

The Clinical Application of Psychological Tests

Diagnostic Summaries and Case Studies. Foundation Monograph Series no. 6. ROY M.A., staff psychologist, Austen Riggs Foundation. York: International Universities Press. 1948. 30*s*.

THIS monograph—if a book weighing over 1½ rightly so described—supplements two earlier (*Diagnostic Psychological Testing*, 1945) in author collaborated with Rapaport and Gill. present work he describes the performance of in various psychiatric categories on five tests—the Wechsler-Bellevue, Rorschach, apperception, sorting and learning efficiency, modified word-association test. In a preliminary the typical abnormalities of performance are under diagnostic headings. The remaining two of the book is then given over to the actual case- Regrettably, the author has not been able to data on the abnormalities found in organic brain or mental defect; and, among the insanities, mani both catatonic and hebephrenic types of schizopl are omitted, which reduces considerably the val the summaries in differential diagnosis. The bo mainly notable for the full records of what Mr. Sch patients said ("their verbalised end-products," puts it) in the various test situations. These undoubtedly be useful to the clinical psychologi reference, and they are detailed enough for the assess for himself the interpretations which are fou on them.

How Psychiatry Helps (New York: Harper. Pp. 242. $3).—To a public that seem avid for no what psychiatrists do, this book offers restrained, acc and simple information about current practice in the U States. It is free from what Prof. Nolan Lewis, i foreword, calls "verbal champagne and nicely turned ia tional phrases." Dr. Phillip Polatin and Miss Ell Philtine have included an account of such recent, mo less experimental, procedures as topectomy and thalamot malononitrile administration, and glutamic acid; but make clear what are, in their view, the limitations of method of treatment described. Naturally they show bias, but in the main they provide an unprete jargon-free popular book on psychiatry that does not a the psychiatric reader by mis-statements or the av reader by signs of condescension and of warfare ag some named or unnamed foes.

Nutrition and Diet in Health and Disease (5th Philadelphia and London: W. B. Saunders. 1949. Pp. 45*s*.).—Prof. J. S. McLester's book needs no recomme tion to nutritionists. It is well known and valuable fo broadmindedness, its interest, and its full bibliogra As he says in his preface, another world war made us learn much about the science of nutrition. of the book has necessarily been rewritten—for exar the chapters on the feeding of infants (Philip Jeans) an nutrition in industry (Robert S. Goodhart)—and there new chapter on the feeding of surgical patients (Charle Lund). The chapter on vitamins makes no mentio Gowland Hopkins. We are apt to consider the United St the best fed country in the world, and it is therefore star to read "Evidence of need for closer attention to the ch diet is abundant." The author gives evidence of " concertingly high" incidences of nutritional deficiency anæmia from States so far apart in distance and climat Florida and Iowa. There is still much to do in educa the parents in nutrition, even in the paradise of nutriti

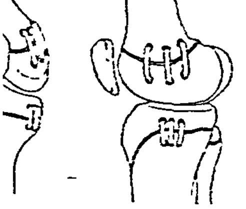
THE LANCET

ONDON: SATURDAY, SEPT. 24, 1949

Shortening Limbs

1932 there were only two surgical ways of g unequal leg length, usually the result of elitis. The longer limb could be shortened ving a segment of one of its bones, usually the ut it was always repugnant to run the risks ting on the sound side. The short limb could hened by performing an osteotomy of the d fibula or the femur, and applying traction ion was taking place. Here again there were essels and nerves from the forcible elongation, often atrophic bone did not always unite. PHEMISTER[1] introduced epiphyseodesis, in rowth at the main lower-limb epiphyses—ound the knee—was permanently stopped by destruction. This again was an operation ound long limb, and very careful calculations be made, from actuarial curves of expected to decide what was the right age for internd whether only the upper tibial and fibular s, or only the lower femoral epiphyses, or all ould be tackled to produce the desired result—legs of approximately equal length by the general cessation of growth. Moreover, if al destruction was incomplete on one side, ar deformity would result—a varus or valgus ill active side forced the plane of the knee-of true. And if the shortening turned out cessive, nothing could be done about it.

5 HAAS[2] showed experimentally and clinically gitudinal growth at an epiphysis could be cally restrained by encircling the epiphyseal h a wire loop, and that growth was resumed wire was removed or broke under the strain on it by the multiplying cells. HAAS sughat leg equalisation, or the correction of a y, might be achieved at an early age more this way than by using the complex estima- PHEMISTER'S method. Now BLOUNT and CLARKE[3] report the results of formal stapling of the epiphyses with three-sided rectangular steel staples (see figure). They find that three are necessary on each side, because one or two will be spread out or broken by the force of growth. It is important to have a radiographic check at the time of operation, for it is easy to insert one of the prongs into the knee-joint by mistake. A separate exposure of each side of the lower femoral and upper tibial epiphyses is made—four incisions in all—and the lower lateral incision is used to curette out the upper fibular epiphyseal plate. The staples are removed when the desired correction is achieved, and they have not so far been left in place for over two years. In cases of improper placement, fracture of a staple, or insufficient correction, the staples may be removed and reinserted. While the three-staple unit is in place growth at that side of the epiphysis pretty well comes to a standstill. After the staples have been removed growth is resumed, apparently at about the normal rate. Premature epiphyseal fusion does not occur if the integrity of the plate is respected at the time of operation.



es inserted into femoral and
piphyses to check growth.

What is particularly attractive about this new method is that correction of leg inequality can be tackled at once, though not usually before the eighth birthday, without waiting to see how matters develop, and it can be repeated if necessary. In addition, it provides an effective means of treating such asymmetrical deformities as fixed genu valgum or varum, and flexion or recurvatum deformity of the knee. For example, a case of knock-knee can be treated by stapling only the inner side of the lower femoral epiphysis, and in a few months correction will be complete and the staples can be removed, after which growth proceeds normally. The relative ease and simplicity of BLOUNT and CLARKE'S new procedure will certainly make it popular, and other applications to the upper limb and elsewhere are probably even now being tried by enthusiastic surgeons. Meanwhile the procedure remains experimental and staples should be inserted with care, for penetration of joints or total interruption of growth due to careless technique are hazards to be avoided.

Progress with Vitamin B_{12}

THE chemical constitution of vitamin B_{12} remains unknown, but increasing supplies have allowed more information to be gathered about its action. The apparently pure crystalline form is contained in liver; and, despite the expense and wastefulness of the process, a few firms both here and in America are now able to provide small amounts from this source. The alternative source—cultures of *Streptomyces griseus*[1]—has also been developed. The activity of concentrates from these cultures has been estimated by their growth-promoting potency for *Lactobacillus lactis* Dorner; and a crystalline product prepared from these concentrates resembles that from liver and seems to have exactly the same clinical activity.[2]

There is no doubt now that vitamin B_{12} from either source will produce a typical remission in pernicious anæmia, nutritional macrocytic anæmia of the southern U.S.A., and West Indian sprue. The dose needed for a proper remission is estimated by SPIES and his colleagues[3] at 100 µg.; and JONES, DARBY,

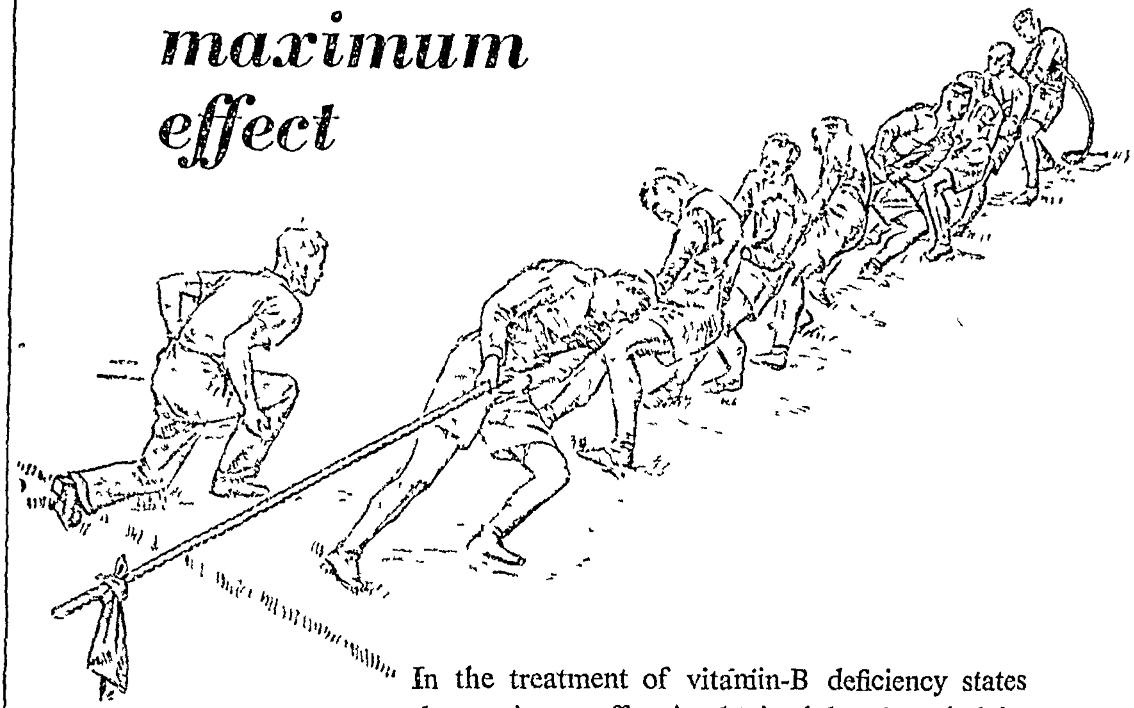
Towards maximum effect



In the treatment of vitamin-B deficiency states the maximum effect is obtained by the administration of a well balanced preparation containing the vitamin-B complex.

The characteristic symptoms which mild deficiency of this complex produces, including anorexia, loss of weight, constipation and depression, respond rapidly to the administration of Befolin Tablets.

When the diet is restricted or when the dietary intake does not meet an increased demand Befolin Tablets A&H supply the ideal supplement.

BEFOLIN A&H

Each tablet contains:

Aneurine hydrochloride ..	1·0 mg.
Riboflavine	1·0 mg.
Nicotinamide	20·0 mg.
Folic Acid	1·7 mg.

Supplied in bottles of 25 and 100.

Literature on application.

Opinions of the N.H.S.

KING to the Physiotherapists' congress last n national schemes of medical care, Dr. J. A. ES doubted "whether any contemporary subject parable social importance has received anything e same amount of attention, has stimulated thought, or is provoking universally more stations of human emotion."[1] It being so, ld be useful both to present inquirers and to historians to have the *Practitioner's* review of tional Health Service's first year.[2] It takes m of a symposium by anonymous contributors, as being "outstanding in their own spheres," "an intimate knowledge of the working of the nd being free, "so far as possible, from preju- Actually, as was to be expected with so many , the articles are uneven, and though most are ly objective, some can hardly claim to sustain m from prejudice, be it against the Government, inst other workers in their own or in rival es of the profession. In fact so much does contributor reveal of the problems and dis- ctions of his section of the profession, and so do these troubles coincide with, or even overlap, of the group next considered, that the reader is ell aware that the first year has brought ttled pattern, and that much remains to one before the service can develop its full tial.

symposium begins with a fair review of major s, relating how the hospitals were taken over, ending their administration in large regions the regional boards, and describing the diffi- s met in the grading of medical staff and in ing establishments. It regrets that for general ice there is no sign of the promised health centres, emphasises the very real danger that the good tions of the Act will founder on the rock of e. The physician who writes next finds "no nce that the health of the nation has benefited the first year" of the service; nor does it appear he has found or sought any greater opportunities ving better service to his colleagues or his patients. d he seems more concerned with judging the nt fluctuations and future trend of private ltant practice, and with suggesting ways whereby that he thinks poorly remunerated (such as ciliary visits) can be relegated to junior col- es, and entirely unpaid ones (such as committee) to whole-time consultants. The surgeon, ly, is more forward-looking and sees in the Act amework round which, given vision on the part ccessive Ministers and an enthusiasm based on dence on the part of the surgeons themselves, a ce second to none can eventually be built." The se "successive Ministers" is worth noting, for too many commentators on the service have ght of it only as the immutable imposition of present Ministry rather than as a malleable nisation changing with the changing needs of the le and of the profession. The obstetrician, though ing with caution and objectivity, lays possibly too much stress on the difficulties arising through the present division of responsibility for maternity services between regional board, local health authority, and executive council; he probably overestimates the advantages that might come from placing the whole hospital and domiciliary service under an already harassed regional board. In the thoughtful contribution from a country practitioner it is a little disconcerting to find resistance to the general view that country cottage hospitals should in future have regular visits from consultants: "no doctor of any character will be content for the rest of his days just to dance attendance on specialists or consultants as a 'clinical assistant.'" A town practitioner brings out the need for a number of changes such as the lowering of the maximum number of patients allowed on a doctor's list, the increase of the capitation fee, and the early provision of health centres.

Two newly qualified doctors help to remind us of the different conditions under which they are entering medicine; not only is there more competition to obtain and keep their place in their teaching hospitals, but the time spent in the Services and in obtaining higher diplomas leads to a later start in independent practice. The ophthalmologist who follows succeeds at least in displaying the magnitude of the problem facing his specialty and in demonstrating how long it must be before the full and permanent ophthalmic service, based on the hospitals, can be established: until which time the supplementary ophthalmic service, with its expense and its shortcomings, must remain with us. The dentist gives an interesting factual survey of the development of the dental service, and shows all too clearly how the service to mothers and children, which was meant to have highest priority, has in fact been sacrificed to the general dental services, and how even here careful conservative work is at a discount. His conclusions are perhaps too pessimistic, but we can all agree with his dictum that it is "scientifically wrong, as well as economically unsound, to provide dentures for octogenarians while allowing the teeth of the rising generation to be neglected."

The medical administrator who writes the next article is obviously a senior officer of a regional board: he has seen much of the evolution of the hospital service, and his experience is so well described that it makes a valuable record. He appreciates the volume of work undertaken by the members of the regional boards, and says that "no praise is too high for them and for those members of the medical profession who have helped so materially and so unselfishly in the planning of the service by their work on advisory committees of all kinds." The contribution from the Ministry itself is largely a factual and historical survey, which helps to put the rest in perspective. After which comes an article, on the service in Scotland, which is in many ways the best in the series: besides commenting shrewdly upon the differing methods, customs, and statutory requirements of the two countries, it gives in small compass an excellent survey of the interdependent development of the hospital, consultant, general-practitioner, and public-health services in Scotland, with telling remarks on each.

Among the other contributions is one from an almoner pointing to the advantages the Act can offer

and TOTTER[4] suggest a dose of 3 µg. daily for six weeks, and then a maintenance dose of 1 µg. daily, to be given parenterally. These doses are somewhat larger than was anticipated.

Does vitamin B_{12} succeed where folic acid fails—namely, in countering the neurological complications of pernicious anæmia? The evidence is still slender. We have already referred[1] to the single case described by BERK and his associates; their patient responded rapidly, but symptoms had been present for only 11 days. HALL and CAMPBELL[5] described 6 cases; in 3 improvement was rapid, but in the other 3 it was not so noticeable. SPIES and others[6] treated a single patient with severe neurological signs; he could not walk and the plantar responses were extensor. He received 100 µg. parenterally, and after five days he could walk and the plantar responses were flexor. In a later paper SPIES and his co-workers[3] gave notes on 14 patients with pernicious anæmia and neurological complications; in 9 symptoms were severe and in 5 mild. Vitamin B_{12} given parenterally caused "dramatic" improvement within ten days. One man had a neurological relapse while being treated with folic acid. He had very stiff and weak legs and hands and severe rombergism; 125 µg. of the vitamin caused notable improvement, with the disappearance of Romberg's sign, by the tenth day. These results are certainly encouraging; and none of the curious neurological relapses associated with folic-acid treatment have so far been recorded. However, judgment is still difficult; for some patients with combined system degeneration do not recover completely even with the most thorough liver treatment, and no reported case treated with vitamin B_{12} has been observed for longer than three months.

Side by side with the clinical trials, workers have been trying to find out how vitamin B_{12} acts, and whether there is substance to the claim that this is in fact the anti-anæmic liver principle. BERK, CASTLE, and their colleagues,[7] at Boston, gave a very small dose—5 µg. daily by mouth for ten days—to patients with pernicious anæmia in relapse; there was no response. But when this dose was given together with 125–150 ml. of neutralised normal human gastric juice, there was a reticulocyte response followed by some rise in the red-cell count. These results were confirmed by HALL, MORGAN, and CAMPBELL,[8] who showed—once again—that gastric juice alone is inactive. The Boston workers found that in an untreated case of pernicious anæmia the fæces contained fairly large quantities of vitamin B_{12}; and this finding has been repeated in 4 further cases.[9] CALLENDER, MALLETT, SPRAY, and SHAW[10] found that the substance extracted from the fæces reproduced the effect of vitamin B_{12} when injected parenterally into a patient with pernicious anæmia in relapse; there was a typical reticulocyte and the megaloblastic marrow was transform normoblastic. They estimated the amount of excreted at 65 µg. per 200 g. wet weight (an a daily excretion). The American workers that the "intrinsic factor" (hæmopoietin) of juice promotes absorption of vitamin B_{12} with the food, or more likely synthesised by in the intestine. They suggest that the vit as an "extrinsic factor," and deny that the anæmic liver principle is normally formed b specific reaction between the intrinsic and factors. SPIES and his co-workers[11] have now lished that vitamin B_{12} is active orally if the large enough; in their experience 30–60 amount of the parenteral dose is needed; patient with pernicious anæmia responded 450 µg. daily for ten days. This supports the that absorption of the vitamin is defective in anæmia, since the dose required seems to be siderably in excess of the daily excretion of B_{12} untreated patient.

Of the three substances—thymine, folic acid, vitamin B_{12}—that have proved capable of megaloblastic erythropoiesis back to normo vitamin B_{12} comes closest in its activity to extracts, in both pernicious anæmia and the mental macrocytic anæmia of rats described WATSON, CAMERON, and WITTS.[12] This experime anæmia, produced by an intestinal short-circu operation, was designed in the hope that the an animals could be used for the assay of liver extr But WATSON and his colleagues, together with C LENDER,[13] find that a purified liver extract ev only an irregular hæmatological response and does prolong the animal's life, whereas folic acid prod an excellent response in both respects; the actio vitamin B_{12} resembles that of the liver extract not that of folic acid. We are still not certain vitamin B_{12} is identical with the anti-anæmic l principle, and the discovery of folic acid has wa us that there exist in nature substances that transform megaloblastic to normoblastic ery poiesis but which may play no part in the ætio of the human pernicious-anæmia syndrome. evidence suggests that in fact vitamin B_{12} is not liver principle. DEDICHEN and LALAND[14] poin out that liver extracts act on the granular white c whereas this vitamin does not. More disturbing reports that the anti-anæmic activity of a given l extract does not run parallel with its content vitamin B_{12} assayed bacteriologically.[15] If B_{12} not the natural liver principle, then explanations the ætiology of pernicious anæmia based on its p perties may well conflict with those based on properties of liver extracts. Speculation is perh premature; but already it seems that in vitamin we may have a reliable means of treating pernicious-anæmia syndrome; and its high cost m be reduced by manufacture from bacterial sour instead of from liver.

high places that it will be provided. It would help ase the very difficult decisions these doctors now make if a guarantee of an annual, or at a biennial, review could be given, and given oritatively and quickly.

EATMENT OF CEREBRAL CYSTICERCOSIS

L medical diagnosis necessarily implies both site ætiology of lesion, but neurology lends itself most itly to such a division; for whereas the site can be surmised with some accuracy from clinical ngs the nature of the lesion is apt to be more elusive. sed to be so with the signs and symptoms caused rebral cysticercosis. During the last two decades, ver, knowledge of and interest in this condition, result, especially in England, of the work of Sir iam MacArthur and others in the Army Medical artment whom he inspired,[1 2] has made its clinical nosis less tentative though still often inferential. y workers consider that cerebral cysticerci while are clinically silent, unless the space occupied by large cyst or many small ones is big enough to cause ct pressure effects. When they die, the cysticerci duce toxins which cause a surrounding inflammation. n by focal or general neurological signs. It may thus omparatively late after infestation that the condition nts clinically. Even then, unless the dead cysts fy, which they may do only long after their death, r presence has to be deduced from indirect evidence. most important indirect pointer is a history of residence in an area known to be heavily infested with icerci. One of the commonest cerebral manifestations e condition is epilepsy, which may have a distinctive ency to be of focal onset but with evidence of more n one focus, perhaps representing variously situated s. Seizures of unusual pattern may thus be a nd diagnostic point. Palpable or radio-opaque les in muscles or subcutaneous tissue, eosinophilia, a positive skin reaction to test fluid may also help.

hen the diagnosis is made, is anything more than ptomatic treatment possible? The question is not ly academic, for the disease is likely to be more mon in this country owing to the large numbers of tish troops who served in the Far East. In the past, nned neurosurgical intervention has been rare, ause the removal of any large number of cysts was wed as technically difficult and often undesirable; ugh cysticerci have occasionally been discovered at ration for the relief of raised intracranial pressure or signs suggesting a localised neoplasm. Now Stepien Chorobski[3] from Warsaw review the operative atment of the condition in 94 cases—23 of their own 71 that they have gathered from the published rk. They divide these into three groups, based on intracranial changes caused. In the first group, gle or a few localised cysts produce symptoms similar those of a cerebral tumour; in the second, widespread estation leads to generalised swelling of the brain; d in the third, a strategically placed cyst or a leptoeningitic reaction to the parasites obstructs the flow cerebrospinal fluid, and internal hydrocephalus results. e division seems sound both clinically and logically; ough, as the writers admit, cases are not always clearut. In their own 23 cases, 11 presented in the first group, in the second, and 7 in the third, while in the 71 other ses the grouping was 52, 2, and 17. As might be pected, the results of operation were best in the first oup—41 cases from the two series recovered or proved, whereas only 2 cases in the second group and in the third were benefited. The operative procedures used by Stepien and Chorobski were the turning of a bone flap with removal of one or many cysts (they record up to 30 in one case), simple decompression, and in some cases of their third group the Stookey operation for the relief of internal hydrocephalus. It must be borne in mind that seizures caused by cysticercosis tend to die out spontaneously. But the findings in this informative paper suggest that the value of neurosurgery has been underestimated in the past. Correct diagnosis becomes the more important, for *treatment will be effective only in cases recognised preoperatively.* This was so in 20 of the 94 cases reviewed. In Britain, thanks to the stimulus of MacArthur, the diagnosis is probably made more often. In many cases, however, operation without precise diagnosis will be undertaken as heretofore, because the clinical picture is one of increasing intracranial pressure with or without focal signs.

Two incidental observations are worth noting. First, epileptic seizures were recorded in 32 of the 73 cases in which information about focal symptoms was available; those seeing cases over here would expect the incidence to be higher. Secondly, pronounced improvement in signs and symptoms sometimes followed the removal of what must have been a trivial proportion of the total cysts present, *suggesting that simple decompression may* have been the more important therapeutic factor.

EXPERIMENTAL TRANSMISSION OF RUBELLA

THE hazard to the fœtus of maternal rubella was first indicated, in 1942, by Gregg,[1] of Sydney; and now, from the Walter and Eliza Hall Institute, Melbourne, Anderson[2] gives a detailed account of his work on a method which may open the way to reducing or even eliminating this risk.[3]

So far there has been little experimental work on rubella, owing to its comparatively low infectivity, the absence of a specific test of susceptibility, and—until Gregg's discovery—its apparently innocuous character. In 1942, Habel[4] transmitted rubella to rhesus monkeys (*Macacca mulatta*) with blood and nasal washings administered by the nasal, subcutaneous, intraperitoneal, and intravenous routes. Fever and leucopenia commonly appeared in eight days, and the virus could then be recovered from the blood whether or not a rash was present. Membrane suspensions from inoculated eggs proved infective, but no obvious lesions were found in the chorio-allantois of the developing chick. In 1938, Hiro and Tasaka[5] had transmitted rubella to children by injecting subcutaneously the filtered throat washings from established cases: of 16 children presumed susceptible and injected in this way, 4 developed typical rubella while 2 showed the characteristic leucopenia and lymphadenopathy without rash. In these experiments the incubation period was short—seven days in 3 cases, and eight days, eleven days, and seventeen days in 1 case each. With natural transmission the average incubation period is fifteen days; and it is not clear whether these workers excluded the possibility that the child who fell ill seventeen days after planned exposure, was naturally infected from one of the successfully inoculated children.

In volunteers inoculated by the respiratory route with infective throat washings, Anderson has obtained almost 50% of "takes"; and he concludes that those who escaped must have undergone previous infection, subclinical or unrecognised, since none contracted the disease when subsequently exposed. Stored at −70°C, the virus in throat washings remained active for at least ninety days. The preparation was thawed and treated with penicillin, or diluted with saline and passed through the hospital patient but also to the way in which it can be abused:

[4] Habel, K. *Publ. Hlth Rep., Wash.* 1942, 57, 1126.
[5] Hiro, Y., Tasaka, S. *Mschr. Kinderheilk.* 1938, 76, 328.

> "It is a great pity that the Act, with its fine basic principle that no person shall by lack of means be debarred from any necessary medical advice or appliance, which has already lifted the burden of financial anxiety and brought to many of our poorest patients comforts and amenities formerly quite beyond their reach, should be so exploited and discredited by a noisy and self-seeking minority."

She is followed by a layman who pays the tribute of a satisfied customer:

> "To sum up my impressions of a year's experience. I can see that to middle-class families, it is not just a benefit, but a necessity; the cost of living has risen so greatly since 1939 that private medical care would be another increasingly expensive burden. I have not lost sight of the fact that I have increased contributions to pay not only for myself but for my staff, and that taking these into account, I am very likely paying more per annum than the amount I *should pay for the whole family as private patients in* what could be called a 'healthy year.' But it is the freedom from worry over the larger items in the health bill, such as major operations and their attendant expenses, that makes the contribution money well spent."

So it seems that he, as an individual, thinks his money well spent and that he can afford so to spend it; but the real question remains, is the money spent by the nation on this service well spent, and can we, as a nation, afford to go on using our resources on the service at the present high and rising scale? An attempt to examine if not to answer this question is made in an article written by a member of the editorial staff of the *Economist.* This surveys first the financial estimates and shows how underestimation of the extent of the demand on the service led to gross underestimation of the likely cost of all sections of the service—except only the general-practitioner service, which, being tied to a capitation method of payment, has not shown the increased cost that would by now certainly be falling on the nation had the medical practitioners, like their dental and ophthalmic colleagues, been paid by item of service. Commenting on the global sums now being spent on these three sections of the service, the economist remarks:

> "Something has gone wrong with the priorities within the Health Service itself when it is possible to estimate the worth of the services of the general practitioner, twenty-four hours a day the whole year round, no higher than the cost of providing dental treatment and spectacles."

Even more interesting and even more worrying than the analysis of the cost of the service in money is the parallel analysis of its cost in man-power, or (worse) in woman-power. The total number of women aged between 15 and 40 in the population will, it is calculated, fall, between 1946 and 1951, by 374,000. Everything we are doing to shorten the hours of nurses, to improve the student status of junior nurses, to multiply ward orderlies, to extend the radiological, pathological, and physiotherapeutic services, to say nothing of our growing clerical and administrative demands or of our programmes for building and staffing new hospitals and health centres, draws to the health services an increasingly large share of the woman-power in this diminishing pool. The competing demands of industry, commerce, education, and the other professions may make it impossible to step up the recruitment of women to nursing, midwifery the ancillary health services without interfering where with another equally important secti national effort. It is very tempting for us who inside medicine, and understand its national i tance, to assume that whatever happens health s receive precedence over all else; but it is saluta us to ponder the economist's dictum that "a c can only have the standard of living it can pay and the standard of living includes the Na Health Service as one of its components, but onl and not one with an overriding priority."

Altogether the *Practitioner* is to be congrat on producing a readable and illuminating symp Whether it will be as well understood by lay here, or by professional readers abroad, as w hope and intention of its authors and editors is a doubtful, even though appendices supply a sur *the Act, a sample of the all-too-familiar* Minis circulars, and a chronological table or "panora of British public health. Nevertheless even the u formed reader must be impressed by the amoun preparation and planning that has already gone launching the new scheme. He may gain the im sion that the launching was a little unsteady and much remains to be done before the ship is pletely fitted out, let alone sailing on an even k but he will at least see that there is no lack of exp each well aware of the shortcomings remaining i own department, and each eagerly seeking remedy.

Annotations

REGRADING

THE reviewing committees have now reached t decisions on the appeals against former grading, an an appreciable number of cases they have found re to revise their earlier verdict. But many men women undertaking specialist tasks are still grad senior hospital medical officers. As is pointed out letter we publish this week, many of these now an unenviable decision: shall they accept the perm contract which they will shortly be offered, thou carries lower status and lower remuneration than were expecting, or shall they break the ties they formed, often over years, for themselves and families in the district of their choice, and seek in o competition a post elsewhere that would make th consultants? What they most fear is that accepta now of a post in which they are graded S.H.M.O. place them permanently in that grade.

A "general post" of such doctors, entailing the break of happily and usefully established relations betw them and their hospitals, their patients, and th colleagues in general practice cannot be for the good the service. Many of these men have been denied hig status only because they are relatively junior and claim no very long experience of specialist work. W proper opportunity and encouragement this experien can often be acquired as well in their present milieu in another. What they need, and what they lack, is firm assurance that if they do continue to serve in the present posts there will be a regular and recurre review of their grading, so that they will have a genui chance of passing into a higher grade when they ha proved themselves further. Everybody seems to agr that such a mechanism for regular regrading will essential, but nobody seems to have unequivocally sa

MEDICAL CARE TODAY

GRESS REPORTS FROM HOME AND ABROAD *

J. A. Charles
M.D. Durh., F.R.C.P., D.P.H.
EPUTY CHIEF MEDICAL OFFICER, MINISTRY OF HEALTH

two national patterns for medical care are lical, and the various problems thrown up by individual systems in operation are resolved by iods and devices which are characteristically national. larly the reactions of the community, of the medical ssion, and of the ancillary workers all bear a onal stamp. It therefore seemed to me that we it benefit from a quick look at some of the trends tendencies in France and Sweden (two countries well-established systems of social insurance); that eafter we might follow the United States in its itable movement towards the inception of some form idely extended medical care; and that finally we ht consider the significance of anything we have ned, in relation to our own now recognised and blished achievement.

France

doubt whether any international comity would be rbed, even mildly, if I were to disagree with Sterne. matter of medical care is not one that they order er in France.

rtually the entire population of France is now com- ed within the Assurance Sociale, for which contri- ons are levied at the rate of 16% on the net income, to a set maximum. Local committees, demo- ically constituted, administer the collected funds. se committees are linked regionally so that the ncial burdens may be equalised between the several stituent districts, and the whole organisation is ject to governmental control and audit. The local mittees are composed of representatives of insured ons, employers, and family associations, with two tors in an advisory capacity.

he system of Assurance Sociale embraces unemploy- nt relief, family allowances, old-age pensions, cash ments during illness and maternity, death benefits, an itemised schedule of payments for medical and tal care. This last requires mathematical skill and graphical knowledge for its elucidation: for example. fee payable for a consultation differs according to ther it is given by a general practitioner or a ialist or a member of the staff of a teaching hospital, again according to whether the patient is living in is or, shall we say, Boulogne or Marseilles. The nch regard their system, despite its large staff of ctionaries, as less bureaucratic than ours. It is cer- ly less comprehensive, for its responsibilities do not ude the administration of hospitals, or any substantial re in the field of preventive medicine. In the case hospital patients contributions are made towards the t of their maintenance and medical care but this is a ent development.

et us look at the general arrangements, from the point of the doctor and the citizen in turn.

THE DOCTOR

he French doctor conducts his practice in accordance h an official code which enjoins:

ree choice of doctor by the patient.
reedom for the practitioner to prescribe.
Direct dealing between patient and doctor in the matter of fees.
Payment direct by the patient to the doctor of the fees due.

But these principles are subject to the reservation that their observation shall not interfere with the reasonable performance and normal development of the services or the introduction of social medicine.

In actual fact the principles have been consistently recognised, though close adherence to them has probably contributed to the financial debility of the scheme.

The free choice of doctor is an idea to which the patient is even more devoted than his physician. Confidence flows from this free choice, and it is claimed that in the absence of that confidence diagnosis and the institution of treatment may become difficult and in *certain cases impossible. Furthermore, the atmosphere of confidence once established will enable the doctor to reassure his patient, to take on his shoulders the patient's own fears, and to shield him from untimely examination and useless treatment even if the patient should himself demand them.*

Freedom in prescribing also adds to the security and confidence of the patient, but here the French have been a little less metaphysical. The scheme pays 80% of the cost of ordinary drugs, but only 40% in the case of special proprietary medicaments. This latter is probably a wise provision, for the Gallic zest for therapeutic variety leads the doctor to prescribe something between 40% and 50% of his medicaments in the form of proprietary pharmaceuticals. Even with us that proportion is no more than 12–15%.

Direct contact between patient and doctor in the matter of fees was long held to be such a fundamental assumption that it was never discussed. It was felt that it gave the doctor an opportunity to be charitable to the poor, reasonable to the middle classes, and appropriately demanding on the rich—though in practice it was often found that the last were not inclined to give more than an adequate recognition for services rendered. Today direct payment of fees by patients is regarded in France as the great bulwark against the institution of a salaried service and medical officialdom. The general arrangement is that the doctor charges his patient according to the official tariff, and the patient is reimbursed 80% of his expenditure by the local fund.

The official tariffs are negotiated freely between the local funds and the doctors, and are ratified centrally. Capitation fees are anathema to the French doctor; they are regarded as introducing an element of speculation which, like payment by results, should be alien to any code of professional remuneration.

THE PATIENT

The patient has, generally speaking, a service which meets the normal needs of himself and his family. He (and they) can use the same general practitioner, to whom he will pay a fee every time he receives attention either at his own home or in the doctor's consulting-rooms—recovering 80% in due course. He can move from the general practitioner to the specialist, and see the latter in his private consulting-rooms, paying a standard fee and being reimbursed in due course. He can be pathologised, or X-rayed, or appropriately cared for by the physiotherapist. He can obtain on prescription through the pharmacist all the medicaments reasonably necessary for his treatment. His wife can be attended during confinement either by a doctor or by the midwife. Under all these circumstances the established basis of payment of 80% by the funds and 20% by the patient, unless indigent, holds good. What does he lack?

Probably the most outstanding deficiency is a well-found hospital service. French hospitals, with a few renowned exceptions, fall short of the standard which we find in this country, in Scandinavia, and in the

xtracts from the opening lecture at the annual congress of the Chartered Society of Physiotherapy, delivered on Sept. 14. The lecture will appear in full in the November issue of *Physiotherapy*, the journal of the society, whose address is Tavistock House (North), Tavistock Square, London, W.C.1.

a fine membrane, before being sprayed into the volunteer's nostrils and oropharynx. In one experiment a laboratory worker standing at least ten feet away from this spraying operation, contracted rubella; so the minimal effective dose was probably much smaller than that actually given. In these experiments the incubation period ranged from thirteen to twenty days, and sometimes lymphadenopathy preceded the appearance of the rash by as much as six days. In general, the longer the incubation period the milder was the attack. Attempts to transmit the disease to 9 subjects who had had a natural attack 6–9 years before, failed; and it was concluded that the induced disease conferred a like immunity, which would cover the average childbearing life of modern women.

Probably, however, this method will not come into general use until the risk of inadvertently transmitting other virus diseases—notably poliomyelitis—is excluded. Meanwhile it is a relief to learn that vaccination has been exonerated from suspicion of causing harm to the growing fœtus.[6]

AURICULAR FIBRILLATION IN NORMAL HEARTS

OVER thirty years ago English workers[7] pointed out that auricular fibrillation may arise in patients whose cardiovascular system seems otherwise normal; and of 651 cases of auricular fibrillation lately studied at the Lahey Clinic by Hanson and Rutledge,[8] 30 (4·6%) were in patients with normal hearts.

Of these, 10 were established cases and 20 paroxysmal. All the established cases and more than half of the paroxysmal were in males. The age at onset varied considerably, but two-thirds of the established cases were in patients aged 30–40, whilst the paroxysmal form tended to appear a decade or so later. Three-quarters of the paroxysmal cases were associated with "a psychogenic or functional element," but in the established cases no precipitating factor was found, and indeed four-fifths of the patients in this group were unaware of the arrhythmia and had no symptoms; all had a relatively slow ventricular rate (60–90 per minute) with no appreciable pulse-deficit. Of the paroxysmal cases, the great majority experienced palpitations during an attack; and then, in nine out of ten, the ventricular rate ranged from 70 to 110 per minute.

The prognosis in such cases is excellent.[9] In this series no patient suffered any incapacity because of the arrhythmia; and in 2 cases established auricular fibrillation had been present for over 40 years when the patients were first seen. Once established, the arrhythmia tends to persist. Of the paroxysmal cases in this series, one became established spontaneously and 2 following digitalis therapy. More than a third of these patients received no treatment. Should treatment be required, quinidine is the drug of choice, although digitalis may sometimes be of value. Assessing the effect of treatment in paroxysmal auricular fibrillation is often difficult, since paroxysms tend to be irregular. As Hanson and Rutledge point out, quinidine is a potent drug which is not altogether non-toxic—a fact that should be borne in mind when considering its use in an otherwise healthy person whose only complaint is of palpitations during a paroxysm.

The ætiology of this interesting condition is obscure, though there is some evidence that it originates from a nervous reflex. Perhaps, however, Hanson and Rutledge are rather rash to say that "auricular fibrillation is a disturbance of auricular impulse formation and conduction that is *a physiologic phenomenon* and a pathogenic one." This is surely stretching the of "physiologic" too far, even for these eclectic In diagnosis the important thing is to exclude presence of *acknowledged* causes of fibrillation especially thyrotoxicosis. Most physicians will than once have seen a diagnosis of "auricular fi in a normal heart" changed ultimately to " fibrillation due to thyrotoxicosis."

TOWARDS GROUP PRACTICE

STEPS towards group practice that seem "de feasible" are outlined in a memorandum to Sc executive councils from the Department of Health, asks for the councils' comment in two months' "There are," the Department rightly says, " gradations between the fully developed health with its special building, complete staff and on the one hand and the purely individualistic handed practice on the other"; and as the large expenditure recedes into the distance it is ingly important to see what can be done with material changes. Thus "it might be possible to accommodation for the administrative headquarte a group from which the health visitors, district nu and midwives could work, which would form the ce for receiving and distributing messages, and which wo house any necessary clerical staff. . . . Even in the of any special buildings at all, arrangements made among the group of practitioners for relief d sharing of clerical assistance, and more intimate coop tion with health visitor and district nurse."

More specifically, the recommended developme include (1) extension of the mutual assistance betw practitioners to mutual relief in off-duty perio (2) arrangements among a group for the receipt telephone messages for any of their number who are n immediately available, and provision for the calling a deputising doctor in urgent cases; (3) coöperation neighbouring doctors in the employment of clerical as tance; (4) the provision of simple laboratory and oth aids to diagnosis for the benefit of a group where provision would not be possible for an individual prac tioner; (5) coöperation between a group of practitione on the one hand and district nurses and health visit on the other, by arrangement between the group and t local authority; and (6) arrangements between grou of practitioners and hospital units for consultati references, clinical discussions, and ward visits.

The memorandum, which is framed on recomme tions from the Scottish Standing Advisory Committ on General Practitioner Services, acknowledges th practitioners themselves must decide the extent to whic they adopt group practice; but it insists that son authority with local knowledge must be responsible f developing practice along these lines, and this duty, says, should rest with the executive council, workin closely with the local authority and the local medic committee. It may be doubtful how far local-authorit and general-practitioner services can be integrated i the absence of a single building from which both ca operate; but the attempt is worth making. Certainly as isolated experiments have proved, a great deal can b done to improve conditions of general practice if practi tioners will join together to do it; and we hope tha much will come of this new Scottish initiative.

THE INDEX and title-page to Vol. I, 1949, which wa completed with THE LANCET of June 25, is now in preparation. A copy will be sent gratis to subscribers on receipt of a postcard addressed to the Manager of THE LANCET, 7, Adam Street, Adelphi, W.C.2. Subscribers who have not already indicated their desire to receive indexes regularly as published should do so now.

h stem from the historic Poor Law Act of Elizabeth eby the truly indigent is provided with the necessities ie, and is cared for in illness and infirmity. But arrangements have, as they had with us until our m of social insurance and the National Health ice Act abolished them, a taint or savour which es unpalatable the service they provide.

art from this public assistance and the organised ic-health service, medical care in the U.S.A. is a ter of free enterprise. The general practitioner and specialist collect what the traffic will bear. The ntary and private hospitals must pay their way. In old days the contribution of the charitable no doubt t some distance towards defraying the annual costs he hospitals; but more and more during the present tury they have only found it possible to make ends t by selling bed-space and nursing service at their e. Patients pay the hospital for their accommoda- and maintenance, and make a bargain with their nding physician or surgeon or obstetricians for his ticular form of care. They are also liable in the jority of cases for meeting the fees of pathologists radiologists.

A brief glance at some of these hospital costs will help to comprehend the whole position. The American spital Association has recently published a comparison the average patient-day costs of 14 American hospitals 1888, and of the same hospitals sixty years later. king the average of the whole 14 hospitals, the daily intenance rate in 1888 was \$1.39; last year it was 4.61, a tenfold increase. Translating that latter figure \$14.61—at \$4 to the pound sterling we reach rate of £3 13*s.* per diem, or £25 10*s.* weekly. ese are actual hospital costs and do not necessarily present the rates charged to the patients because most spitals have some additional source of income: but rates charged do not usually fall much short of 10*s.* per day in a ward or £3 10*s.* in a two-bedded om. Add to this medical charges, the cost of con- alescence, the interruption, perhaps, of wage-earning nd one realises how—except for the indigent—serious ness in the United States is both a family and a nancial calamity.

VOLUNTARY INSURANCE

With a view to mitigating these economic pains, there as developed throughout the Union a system of volun- ary insurance against the cost of hospital maintenance hich is called the Blue Cross. There are a large number f such schemes, and they are only loosely linked together. n addition Blue Shield schemes provide insurance gainst the cost of medical care while in hospital, and a mall number of these will also pay the general practitioner's bill. The Blue Cross and the Blue Shield organisations are local non-profit-making bodies, composed of representatives of the hospitals, the medical profession, and the public. In addition, policies of a similar kind can be obtained from an increasing number of insurance companies. Furthermore, one of the recent movements in trade-union policy has been to accept the provision of medical care in lieu of an actual addition to wages. These facts are some measure of the desire to meet the need, and though the figures have not the validity of census data, it is probable that out of a population of 140 million, 40 million are covered for hospitalisation, 20 million are covered for their medical care while in hospital, and 4 million have some form of contractual arrangement with their general practitioner.

ACTS AND BILLS

The government has already taken one substantial step. In 1946 it passed the Hospital Construction Act, under which it is prepared to pay one-third of the cost of all approved hospital construction. These proposals, concentrated in the first instance on the provision of hospitals of 50 beds or less, have already gone a long way to rectify the deficiencies of the rural areas. But the deficiencies are not limited to the small hospitals. In all nearly a million new hospital beds are needed—one-quarter of them for the chronic sick, who, as with us here, have long been standing at the end of the hospital queue. There are deficiencies in professional personnel of all kinds, and of equipment also, though in the United States equipment shortages have a habit of being rectified almost over night.

The Federal Security Administrator, Mr. Oscar Ewing, addressed his famous "Ten Years' Programme for the Betterment of the Nation's Health" to President Truman exactly a year ago. It excited an amount of opposition and criticism, infinitely greater than anything we have experienced in this country. It caused the American Medical Association to enlist the services of two of the most energetic publicists in the country, so that the community should not be unaware of the evils of so-called socialised medicine. The association's policy is that a wide extension of the existing voluntary insurance schemes—the Blue Cross and Blue Shield already mentioned—will do all that is necessary.

Mr. Truman has countered by introducing a Bill for Universal Insurance, based on contributions by the individual wage-earner and salary-earner, his employer, and the State. The insurance would cover over-all medical care of the individual insured person and his immediate family. To begin with, self-employed persons and certain other comparable categories would be excluded; but at least 85 million of the population at least would benefit and the dollar barrier between doctor and patient would disappear. The Bill also provides for subsidies to the medical and nursing schools so that the future shall have its army of professional workers.

There we must leave the United States in the knowledge that nothing ever remains stationary on that great sub-continent.

The N.H.S.

Our own National Health Service has proved to be popular beyond all expectations. 95% of the population have chosen their general practitioners; the indexes of the executive councils include names from every class of society; 95% of the doctors, 90% of the dentists, and practically 100% of the chemists are in the scheme. Every day half-a-million prescriptions are dispensed; 5 million pairs of spectacles have already been provided; 8 million persons have presented themselves for dental treatment. These are most outstanding figures, but in every field the citizen is able to find what he needs for his own medical care or for that of the children, and the charges are no longer referred to him personally.

The over-all cost of the service is estimated in this financial year to amount to £228 million net for the population of England and Wales, which is roughly 2*s.* 1*d.* a week per head. There are those who cavil at this amount. It may be that within this enormous scheme there is the possibility of saving here and there—you yourselves will probably know how efficiency might be maintained in your departments at less cost—but one must see this expenditure against the background of the £300 million which is lost to industrial production each year by illness, before one challenges the need to spend it.

We, together with New Zealand, have established a complete and integrated health service for the whole of our population. Its inauguration has been a stupendous task, but the benefits which the service can bring if we use it wisely and intelligently are great also. Adequate medical care has never been a cheap commodity, and all these other nations, who will tend inevitably to move in the same direction as ourselves, will learn that too. But proper medical care can produce good health, which, like wisdom, is beyond price.

United States. To quote from a native source: "the French hospital still displays the mark of its foundation which made of it more of a refuge than a place of treatment for the indigent, pilgrims, tramps, the lame and the old. It is an establishment for lodging and not for medical care." One fact makes that obvious. If we analyse the daily cost of maintaining a patient in a typical general hospital in this country, we shall find that the amount chargeable to medical investigation and treatment, as distinct from nursing, is equivalent to about 20% of the total cost: in France it never exceeds 5%. The over-all standard of French nursing is at a level which we would hesitate to regard as adequate. Until comparatively recently it was customary for the patient to give gratuities to the nursing staff.

There are various directions in which the French system of medical care is still striving after improvement and amplification. One cannot avoid the conclusion that the completion of that task will add materially to the already mounting cost of social insurance.

Sweden

In Sweden the basis of medical care is twofold. There is organised sickness insurance within a circumscribed field, and a magnificent hospital system, maintained by local and central taxation, which is available to everyone.

As has happened elsewhere, the sickness insurance which commenced as a mutual and voluntary association of workmen or of individuals living in the same locality will become in 1950 a compulsory system covering the whole population. The new service will be an extension of what is in existence now, and the insurance societies will continue to be managers of their funds under government supervision, receiving about half their premium income from the national exchequer. The remaining half will be composed of the family subscriptions paid by insured persons at the low rate of 32*s.* per annum. These funds will cover the cost of sickness payments, of medical benefits, and of maternity subsidies. To help *towards the cost of invalidity and old-age pensions* a further annual levy of approximately £7 a year per family will be made.

Under medical benefit a general practitioner, freely chosen, is provided, and such medicaments (except a limited range of expensive drugs) as are required for treatment. The patient pays the doctor, and recovers two-thirds of this expenditure from the sickness fund.

During recent years the Swedish local authorities, the cities, and the counties have built up one of the finest hospital services in the world. (Mental hospitals, generally speaking, are the concern of the State.) A daily token charge is made for each patient to cover the cost of his food; but even this is remitted for the indigent. The rest is free—specialist care, pathological and radiological investigation, nursing, physiotherapy. Every class of the community uses the municipal hospital, for in the modern hospitals there is a large range of single and two-bedded wards; and though it is possible, as with us, to be treated as a private patient, the inducements to do so are small, and empty beds in the paying section are far from uncommon. Next year even the token payments will disappear, and the hospital service in Sweden will be completely comparable with our own. *This decision to free the hospitals* has been reached despite the fact that hospital costs in 1948 were approximately three times what they were in 1938, and that the weekly cost of maintenance in the average general hospital is of the order of £12, of which roughly 60% represents salaries and wages.

PERSONNEL

What then is Sweden's great problem? It is dearth of personnel in every field—doctors, nurses, and ancillaries.

There are slightly more than 4000 doctors to serve a population of 7 million—a doctor-patient ratio of 1 to 1750 compared with 1 to 1400 in France and 1 to in this country. Medical fees are not high, salaries paid to whole-time staff are moderate standards; but on an average doctors are well up top 5% of the income groups. Their scarcity increased their power as a pressure group and it be a mistake to assume that they have looked future without apprehension or that they have adopted such measures of immediate self-pr seemed expedient. But there are many medical and nurses and others in Sweden who take the themselves only after the claims of public service been satisfied. In the northern counties there are no more than 3 doctors to 10,000 of the populati their territory covers many hundreds of square *Under these circumstances, the individual doctor* be an Admirable Crichton. He is medical officer of general practitioner, specialist, and often and justice of the peace all combined. His salary part guaranteed by the State, and the fees he ch private patients are regulated by agreement. It need to maintain a proper standard of medical these remote parts, and the almost insatiable of the hospital service for more and more medical —physicians, pathologists, specialist surgeons, of the newer techniques of neurosurgery and t surgery, in whose growth Sweden has played a siderable part—which constitute the real crisis in medical affairs. With enlarged medical services demands not only for more doctors but also for physiotherapists, laboratory technicians, and every of medical auxilliary.

The Royal Medical Board of Sweden has that if it is to provide a service of the comprehe *which modern standards of medical care* envisage, will be necessary during the next twelve years to the number of practising doctors from 4200—the total—to 7200, an increase of 70%. The rate at whi the profession is growing now would add no more th 500 during the same period.

Sweden, with her eyes open, and fully aware of t economic burdens which a coördinated and comp hensive health service can place upon a community, nevertheless persuaded that the cost is worth while.

The United States

We have already mentioned two countries expenditure on their health services will inevitably increased if the objectives they have in view are to reached. France will not be able to modernise hospital service without great capital outlay, and complementary increase in maintenance charges. Swede will find that the establishment of additional medica schools, and the fitting out of new teaching hospitals an expensive business. And beyond all that there wil be the ultimate cost of providing for large additions not only to the strength of the medical profession, but to the other ancillary professions also.

The cost of medical care has special relevance in the United States of America. Ten years ago the American Medical Association carried out an inquiry which showed that an annual family income of £750 was not sufficient to bear the cost of a serious or chronic illness. The American Hospital Association, cognisant of the vast increase in hospital costs which has occurred, has attempted for many years to bring the individual citizen and his family within insurance schemes which will at any rate cover the maintenance charges in hospital. The man in the street is aware that unless he makes provision by way of insurance—and at rates which though actuarily fair are nevertheless heavy—he must face the possibility of some catastrophic disaster to his financial stability if major illness besets himself or his family. In every State of the Union there are of course arrangements

In England Now

Running Commentary by Peripatetic Correspondents

s a wet morning the Holiday Camp on the windy ks like an outsize fun-fair before the fun has started. scarlet-coated cheerleaders dart about, busy with arations; the giant clowns in the centre smile down dly on bedraggled campers drifting into chemist, monger, gift-shop, and stationer (the fish and chip is not yet open), or disappearing into "Rhenish" cellars, "Old-Vienna" cafes, and neon-lit snack-bars re, right up till lunch, weak tea and coffee and too large colourful cakes are served on pink plastic to patient ers. The solemn lad at the next table with his ed member's badge wastes no time on thirds and s himself to three vast cream puffs.

en the unquiet fun will be taking its allotted course g while the eye is allowed no rest. Someone has heard t bright colours make for cheerfulness; all the hues he rainbow pursue the campers mercilessly. The ters have splashed buckets of red, green, pink, blue, d yellow on walls, beams, chairs, tables, and counters never-ending contrast. Multi-coloured lights and tering tinfoil borders gleam along the ceilings. Nothing hat it seems: artificial flowers bloom in unlikely ces, bricks are painted on papier mâché; imitation f vistas of Montmartre, mountain scenery, striped ings, and false panelling disguise the concrete walls. t at the end of a summer's fun the disguise is beginning wear thin here and there, the turf has faded, the paint cked. Fun-fairs don't grow old gracefully.

We drift into the dark ballroom where the orchestra ts on a brightly lit stage. The pianist limbers up stalgically with a few bars of Brahms; a trousered ng woman knits her brow over a crossword puzzle. ddenly the loudspeaker booms: "Let me hear you a number please!" The orchestra is convulsed into az. The young woman clutches the microphone just ore melodiously to regret that she can never forget fore returning impassive to her crossword. The music ates. "One o'clock!" the cheerleaders are shouting erywhere. Cafes and ice-cream parlours empty and dient campers struggle through wind and rain towards ir allotted dining-halls. Now all the loudspeakers rt up. They relay announcements while the soup is nded out. Then the orchestra storms into action, its tural gusto magnified to drown all else. Henceforth re will be little quiet except at the "Lads" and Lasses" till after the thousands of campers have sung ir "goodnight song" and retired to their chalets. is will be their last night here—to-morrow they leave. ey look to us somewhat tired, less sun-tanned, less aced by sea and mountain air than the other campers o bathe from their tents on the lonely rocks—or do e all look pale and sickly against neon lights and bright aint?

A friend of mine, aged ten, has probably not heard of ittle Sophie Tuckshop, but she sometimes reminds one ibly of that engaging damsel. She joined us lately n some desultory blackberry-picking, and while most of hat she picked went into her mouth, a few berries strayed into the basket. She told us that she and another irl had been making blackberry wine, and I asked or the recipe—her own invention. Two jam jars of blackberries were filled up with water and the contents crushed: three teaspoonfuls of sugar were added and an unspecified amount of liver salts. I brooded a ittle and then asked if the concoction were not sour. Sophie's double smacked her lips expressively and said it was lovely. She beamed at us and I said darkly that she looked very well. Delicacy forbade any more searching inquiries in the presence of a man.

* * *

The physician-superintendent tells me that I'm to stop nagging about my contract and my back pay. "You know you'll get both sooner or later, so why worry?" he says. But now I have worked out the situation in business men's terms I worry even more. I am a partner in a business and part of the capital is in the form of a loan from the Westminster Bank. The hospital has its own money in the same bank. I pay the bank interest on my loan and the bank pays the hospital interest on the money in its deposit account. So I seem to be lending my salary to the hospital and paying interest on it. The actual cash I have lost already is between five and six pounds. Perhaps not much to the N.H.S. but quite a bit to me.

* * *

The burning question of the day in the country is wasp stings. My own experience started when the baker was stung under my eyes on the hand, as he held out a loaf of bread. He squeezed out the sting and went off cheerfully after I had dabbed some vinegar on the place with cotton-wool; on his next visit he said he had neither pain nor swelling. So far, so good. Next, my morning help, Evelyn, flew in before breakfast with a swollen tongue and suffering from shock. She had been stung while putting a piece of bread-and-butter into her mouth. After glucose and hot tea—although she could scarcely swallow—she revived and I produced, faute-de-mieux, more vinegar in which to lave the tongue. The sting was on the extreme tip and I hoped she would escape œdema of the glottis, but, as I am not a G.P. and have little in the way of drugs or equipment, I rang up her own doctor two miles away to produce, if he would, one of the newer remedies. But he was gently pessimistic: all his patients were being stung and he found little benefit from the anti-histamine drugs: in fact, he thought there was nothing better than the raw onion the patients themselves swore by. Nothing was easier than to fetch a juicy-looking onion from the garden and to watch with fascinated horror while Evelyn sucked slices of it and occasionally sipped her tea, not at all daunted by the combined flavours. I gave her a book and retired to breakfast. After an hour all the soft structures round her neck and jaws were swollen and her ears were buzzing, while a bright red, discrete, and itchy rash was coming out profusely over her face and chest; but she could speak and swallow more easily and declared herself well enough to walk the few hundred yards to her home, where she decided she would spend the day on the sofa, knitting. In a few hours the rash covered her from head to foot, appearing even between the toes, but it had gone by night and so had the swelling. Next day she was as well as ever, and when she was stung again a day or two later—on the finger—she had neither pain nor swelling and seemed to be desensitised.

By one of those odd chances that dog us in life, another girl of the same name was "stung by a wasp and died of shock the same day as I did," Evelyn tells me. One takes her meaning and shares her relief.

Another victim was Evelyn's next-door neighbour, who was stung on the finger. Three hours later a rash appeared; the next day her face swelled, especially the eyelids; and both rash and swelling persisted over the third day, and the swollen eyelids are said to have turned yellow. Evelyn brought daily reports, for it appeared that I was the unwitting villain. Mrs. Next-Door is convinced that neither she nor Evelyn would have had rashes if it had not been for the vinegar. Even Evelyn wavered, for it now appeared that her hairdresser's mother had been stung on the tongue while eating a cream bun on the beach, and at the first-aid station had been given bicarbonate of soda to rinse her mouth, with the sequel that all swelling had gone in a few hours. Post hoc. . . . The moral seems to me to be that, as so often, it is the sensitivity of the patient's tissues to the toxin that is more important than the remedy applied. The country people here believe that the venom of wasps varies from nest to nest, and that members of the same nest who were particularly "strong" stung both Evelyn and her friend—hence the violent reactions. As for me, I am still cautiously avoiding being stung at all.

"Daddy, you're so clever you ought to be a workman, not just a doctor."

THE DENTIST'S DAY

WORKING PARTY'S REPORT

THE Working Party set up under the chairmanship of Mr. W. Penman, to investigate chairside times taken by dentists in carrying out treatment, has now reported.[1] The report suggests that the following picture of the dental profession in Great Britain should be borne in mind:

> "Most dentists are working longer hours than is comfortable, or than would be good for them if continued for too long a period, and many of them are working more quickly than they would normally. These conditions have been forced upon them by the influx of work which has resulted from the expanded health service. As a body, they have been trying to cope with the difficult problem of keeping pace with demand without loss of efficiency and, as a body, the working party thinks they should have received more gratitude and less adverse criticism than has actually been the case.
>
> "Moreover, there is little hope of an early improvement, even if demand should lessen in certain directions. It cannot be doubted that the present volume of work is held down by the inability of the dentists to do any more, and, as was indicated in the Teviot interim report, it will probably be many years before there is any appreciable increase in the number of dentists."

"Human beings," adds the report, "are rarely actuated by a single motive." Some dentists are admittedly working too long, too quickly, and with an eye fixed too closely on the monetary reward—even to the point where their efficiency may be questioned. Up to this point neither the State nor the patient suffers, and the comparatively few cases of very long hours, very rapid work, and very high earnings, though they should be investigated to expose inefficiency or establish efficiency, are not to be regarded as a major factor in considering terms of service.

HOURS AND EARNINGS

The Spens Committee recommended that chairside hours each week should not exceed 33, and the committee estimated that this number of hours at the chairside would involve altogether some 42 working hours. The Working Party's report shows that last April, of 261 dentists in a random sample, 70 were working shorter hours than this standard, 25 were working to about the standard, and 166 (64%) were working longer hours than the standard. This 64% (who are doing 73% of all the work) are working on average rather more than nine hours a day for a $5^1/_2$ day week, and their chairside hours are some 25% in excess of the Spens standard.

As to earnings, the committee finds that on average, before the introduction of the "ceiling" of £400 a month (which has since been abandoned in favour of a reduced scale of fees), dentists engaged in the National Health Service were earning about 19% in excess of the Spens standard. Of this 19%, about 11% is covered by hours in excess of the Spens standard and about 8% by speed of work in excess of that assumed in 1948.

The Working Party is satisfied that the private work done by National Health Service dentists represents only about $4^1/_2$% of their total operations; and it

> "regards that figure as disposing of the suggestion, which has sometimes been made, that any considerable section of the dental profession is using the National Health Service on a substantial scale as a cloak under which to obtain comparatively high private fees, as the price of giving priority of treatment. It is felt that a dentist who was in practice before July, 1948, may very well have a small proportion, such as 4 per cent., of his old clients who prefer, for the present even if not permanently, to retain their old relationship as private patients."

Surprisingly perhaps, an average of $3^3/_4$ taken up in parting with one patient and installin next; and this figure is about the same in private pr as in the service. This time "could not be appr reduced without such a degree of haste as might in discourtesy." On the other hand, the Working P expresses the view that there could be some econ chairside time by such measures as employing a h trained chairside assistant, setting up a second and following a systematic routine.

As the following figures indicate, dentists in priv practice undertake relatively more fillings than th the service:

	Completed operation		
	Fillings	Extractions	Dent
	%	%	%
Dentists outside N.H.S.	38·1	9·3	5
Dentists in N.H.S.:			
Private patients	13·9	42·3	87
N.H.S. patients	30·7	23·3	1

The discrepancy in respect of private patients tre by dentists outside and within the service is attrib "with some diffidence" to private work done by den in the service for people who are in a hurry.

MEDICAL DEFENCE UNION

AT the Medical Defence Union's annual meeting London last Tuesday, members agreed that the su scription be increased to £2. In his presidential addr Mr. St. J. D. Buxton explained that during the l year the membership had reached 33,200—an incre of 1100—and the subscription income was over £30,0 But law expenses and indemnity claims alone cost ov £35,000, and during the last two years the total exp diture had exceeded the income from all sources £20,000. It appeared to the council improvident continue to deplete the Union's invested funds.

> "These figures indicate two things: firstly, that t Union does not hesitate to protect its members, whatev the cost may be, and secondly that to do this a larg income is required. It is known that many memb realise that the subscription rate has remained unchang for many years and are surprised that it has not bee raised. All know that the cost of everything, from da bread to legal damages, has risen. Hence the recomme dation before you is to raise the subscription rate to with modifications in rates of life membership, &c., on approved scale. This policy has not arisen from the expe of one or two cases, but because of the upgrade of costs."

The annual report for 1948, which was presented the meeting, shows that no fewer than 1959 membe sought the Union's assistance, 69 having been accuse of professional negligence. At the meeting Mr. Buxto gave a particular warning about ancillary examinations

> "The patient," he said, "knows little or nothing abou the work of specialists who conduct X-ray, pathological or other examinations. If a member acts on one of thes which happens to be an erroneous report, given in good faith, he may fail in his duty and be charged with negligence with the other doctor as a co-defendant. Hence it is o the utmost importance that consultation with thos carrying out ancillary examinations should be made, at least whenever there is doubt, both for the sake of th patient and the doctor."

Assistance to a member will be given most easily, he added, if he will consult the secretary as soon as he finds himself in a medicolegal difficulty.

Mr. Buxton paid warm tributes to the officers and staff of the society, and also to Mr. Ivor Back and Dr. Henry Robinson, chairmen of committees. Having several times been re-elected president by the elected members of council, he had now, he said, informed them that he wished to end his term of office. He is to be succeeded in the presidency by Mr. Ivor Back.

In England Now

Running Commentary by Peripatetic Correspondents

s a wet morning the Holiday Camp on the windy s is like an outsize fun-fair before the fun has started. scarlet-coated cheerleaders dart about, busy with arations; the giant clowns in the centre smile down ally on bedraggled campers drifting into chemist, monger, gift-shop, and stationer (the fish-and-chip is not yet open), or disappearing into "Rhenish" -cellars, "Old-Vienna" cafés, and neon-lit snackbars re, right up till lunch, weak tea and coffee and too-large colourful cakes are served on pink plastic to patient ners. The solemn lad at the next table with his ured member's badge wastes no time on fluids and lies himself to three vast cream puffs.

oon the unquiet fun will be taking its allotted course. nwhile the eye is allowed no rest. Someone has heard t bright colours make for cheerfulness; all the hues the rainbow pursue the campers mercilessly. The nters have splashed buckets of red, green, pink, blue, l yellow on walls, beams, chairs, tables, and counters never-ending contrast. Multi-coloured lights and tering tinfoil borders gleam along the ceilings. Nothing what it seems: artificial flowers bloom in unlikely ces, bricks are painted on papier mâché; imitation f, vistas of Montmartre, mountain scenery, striped nings, and false panelling disguise the concrete walls. t at the end of a summer's fun the disguise is beginning wear thin here and there, the turf has faded, the paint cked. Fun-fairs don't grow old gracefully.

We drift into the dark ballroom where the orchestra es on a brightly lit stage. The pianist limbers up stalgically with a few bars of Brahms; a trousered ung woman knits her brow over a crossword puzzle. ddenly the loudspeaker booms: "Let me hear you a number please!" The orchestra is convulsed into ing. The young woman clutches the microphone just time melodiously to regret that she can never forget fore returning impassive to her crossword. The music ales. "One o'clock!" the cheerleaders are shouting erywhere. Cafés and ice-cream parlours empty and edient campers struggle through wind and rain towards eir allotted dining-halls. Now all the loudspeakers art up. They relay announcements while the soup is ured out. Then the orchestra storms into action, its tural gusto magnified to drown all else. Henceforth ere will be little quiet except at the "Lads" and Lasses" till after the thousands of campers have sung eir "goodnight song" and retired to their chalets. is will be their last night here—to-morrow they leave. ey look to us somewhat tired, less sun-tanned, less aced by sea and mountain air than the other campers ho bathe from their tents on the lonely rocks—or do e all look pale and sickly against neon lights and bright aint?

A friend of mine, aged ten, has probably not heard of ittle Sophie Tuckshop, but she sometimes reminds one orcibly of that engaging damsel. She joined us lately n some desultory blackberry-picking, and while most of what she picked went into her mouth, a few berries trayed into the basket. She told us that she and another girl had been making blackberry wine, and I asked for the recipe—her own invention. Two jam jars of blackberries were filled up with water and the contents quashed; three teaspoonfuls of sugar were added and an unspecified amount of liver salts. I brooded a little and then asked if the concoction were not sour. Sophie's double smacked her lips expressively and said it was lovely. She beamed at us and I said darkly that she looked very well. Delicacy forbade any more searching inquiries in the presence of a man.

* * *

The physician-superintendent tells me that I'm to stop nagging about my contract and my back pay. "You know you'll get both sooner or later, so why worry?" he says. But now I have worked out the situation in business men's terms I worry even more. I am a partner in a business and part of the capital is in the form of a loan from the Westminster Bank. The hospital has its own money in the same bank. I pay the bank interest on my loan and the bank pays the hospital interest on the money in its deposit account. So I seem to be lending my salary to the hospital and paying interest on it. The actual cash I have lost already is between five and six pounds. Perhaps not much to the N.H.S. but quite a bit to me.

* * *

The burning question of the day in the country is wasp stings. My own experience started when the baker was stung under my eyes on the hand, as he held out a loaf of bread. He squeezed out the sting and went off cheerfully after I had dabbed some vinegar on the place with cotton-wool; on his next visit he said he had neither pain nor swelling. So far, so good. Next, my morning help, Evelyn, flew in before breakfast with a swollen tongue and suffering from shock. She had been stung while putting a piece of bread-and-butter into her mouth. After glucose and hot tea—although she could scarcely swallow—she revived and I produced, faute-de-mieux, more vinegar in which to lave the tongue. The sting was on the extreme tip and I hoped she would escape œdema of the glottis, but, as I am not a G.P. and have little in the way of drugs or equipment, I rang up her own doctor two miles away to produce, if he would, one of the newer remedies. But he was gently pessimistic: all his patients were being stung and he found little benefit from the anti-histamine drugs: in fact, he thought there was nothing better than the raw onion the patients themselves swore by. Nothing was easier than to fetch a juicy-looking onion from the garden and to watch with fascinated horror while Evelyn sucked slices of it and occasionally sipped her tea, not at all daunted by the combined flavours. I gave her a book and retired to breakfast. After an hour all the soft structures round her neck and jaws were swollen and her ears were buzzing, while a bright red, discrete, and itchy rash was coming out profusely over her face and chest; but she could speak and swallow more easily and declared herself well enough to walk the few hundred yards to her home, where she decided she would spend the day on the sofa, knitting. In a few hours the rash covered her from head to foot, appearing even between the toes, but it had gone by night and so had the swelling. Next day she was as well as ever, and when she was stung again a day or two later—on the finger—she had neither pain nor swelling and seemed to be desensitised.

By one of those odd chances that dog us in life, another girl of the same name was "stung by a wasp and died of shock the same day as I did," Evelyn tells me. One takes her meaning and shares her relief.

Another victim was Evelyn's next-door neighbour, who was stung on the finger. Three hours later a rash appeared; the next day her face swelled, especially the eyelids; and both rash and swelling persisted over the third day, and the swollen eyelids are said to have turned yellow. Evelyn brought daily reports, for it appeared that I was the unwitting villain. Mrs. Next-Door is convinced that neither she nor Evelyn would have had rashes if it had not been for the vinegar. Even Evelyn wavered, for it now appeared that her hairdresser's mother had been stung on the tongue while eating a cream bun on the beach, and at the first-aid station had been given bicarbonate of soda to rinse her mouth, with the sequel that all swelling had gone in a few hours. Post hoc. . . . The moral seems to me to be that, as so often, it is the sensitivity of the patient's tissues to the toxin that is more important than the remedy applied. The country people here believe that the venom of wasps varies from nest to nest, and that members of the same nest who were particularly "strong" stung both Evelyn and her friend—hence the violent reactions. As for me, I am still cautiously avoiding being stung at all.

"Daddy, you're so clever you ought to be a workman, not just a doctor."

Letters to the Editor

SEEING THE PATIENT THROUGH

SIR,—Dr. Lipscomb's article last week must have set thinking all those in daily contact with hospitals.

As a general practitioner I am responsible for sending many patients into "hospitaland" and find them often returning confused and crestfallen. They are confused by the number of doctors whose hands they have to pass through, and crestfallen after the long waits and ignorance of the findings at the end of it all. "I will write to your doctor" may give them one comfortable night's rest, but when the doctor has not heard after a week or more, even though he has tried to stimulate the registrars' room, the patient and his doctor begin to ask "Who sees us through from here?"

We send cases to hospital:

(*a*) Because, though we know the diagnosis, treatment can only be adequately carried out in hospital. This class includes most emergencies and usually the patient is "seen through" very creditably.

(*b*) Because we are uncertain of the diagnosis or treatment and require another opinion so that we can coöperate more confidently with the patient in the treatment of his condition.

It is here that any lack of coördination in the "medical world" will be to the detriment of the patient, by tending to arouse uncertainty in his mind and make him lose confidence in those trying to treat him.

Wealdstone, Harrow. L. P. DAVIES.

SIR,—It seems to me that you were too mealy mouthed in last week's leading article. The first assistant "CAN make it his duty . . ." "CAN see to it . . ." "CAN help to achieve. . . ." The chief "CAN" do three things to help the patient's progress to health. "Many of these alterations may be impracticable in an established system." I suggest that MUST be substituted for your CAN; and if the established system makes that impracticable then "Sae much the waur for the coo."

The essential thing is that the man who takes charge of the patient in the outpatient department must remain in charge of him in the wards till his discharge. That of course entails the subdivision of the ward beds so that each outpatient chief has his share, and that there shall be as many outpatient chiefs as may be necessary for the efficient running of the departments, whether medical, ophthalmic, or other. And further no-one shall have beds who does not feed them from his own outpatient list. In addition, all outpatients shall be seen by appointment only, and the chiefs of the clinics must attend punctually and supervise and be responsible for the disposal of all patients of the clinic. These same chiefs should dictate the letters to the patients' doctors whether after outpatient investigation only or after discharge from the wards.

All this may need a revolution in a London teaching hospital, but I contend that if required it would be a beneficial one and it is not impracticable since it works well in a certain large provincial hospital.

Coventry. W. FRASER ANNAND.

SIR,—What a sad story Dr. Lipscomb tells, and how unnecessary it would be if "outpatients" were abolished; if every ambulant patient were brought into the consultation section of the unit; met at first arrival by the team-sister, nurse, house-surgeon, registrar, and consultant; and kept as one of their "children" until he could be finally returned to his own doctor, fit to resume his occupation, sound in mind and body; and how much better still if one of the general practitioners were, in turn, a member of the team.

That was the idea behind the design of the new Westminster Hospital. Whether the ideal is reached maintained is neither here nor there.

London, W.1. E. ROCK C

SIR,—It is remarkable that Dr. Lipscomb should written an article, and you an editorial, on seeing patient through, without mentioning the place of almoner in the scheme of things.

The relationship between the patient and the teaching hospital, with its persistent shortage of its large outpatient consultation departments, and responsibility for the education of students, and nurses, is complex and must be recognised as To be satisfactory it needs not only good intentions also good organisation. In my own unit the now interviews all outpatients whose names are the admission list, to see that they have no unask unanswered questions; she discusses all inpatients the doctor in charge of the ward to ensure that the is true before discharge, and takes part in the follow-up inquiry which is made on all patients months after discharge. The aim of the follo inquiry is to make sure that diagnosis, treatment, aftercare have been fully effective, and, like a sluice a river, it seems to raise the level of social care through the whole preceding period.[1]

The success of the scheme depends on the almo being an integral and permanent member of the not just another service laid on by the hospital. I my impression that it solves most of the difficul mentioned as occurring between the hospital and patient. I claim little personal credit for it. It inspired by an economist who carried out a survey of local hospitals in 1938 and told me bluntly that business would survive for a year if it knew so li about the satisfaction of its customers as we did, and has been devised by the able almoners who have wor with me since. The difficulties between the hospital the general practitioner can similarly be smoothed by good organisation and a medical staff of whom some least have had experience of private or general practic

Radcliffe Infirmary, Oxford. L. J. WITTS

SIR,—Dr. Lipscomb, writing tellingly last week of numerous small breakdowns in our hospitals, states clearly the case for the medical records officer.

The medical records officer is trained to smooth first line of approach of the patient to the hospital. acquaints the general practitioner with outpatient tim and commonly he supplies a convenient form of let on which application for appointment may be made.

He is responsible for the work of the appointme clerks, seeing that they deal sympathetically and inte gently with inquiries; and he makes sure that appoi ments are timed to the needs of the patient and clinician. A trained appointments clerk will tell patient how to get to the hospital, for what to be p pared, and how long to expect to stay. These lit courtesies, which make all the difference, are b carried out by one whose duty it is not to forget them.

With a good appointments system, all medical recor and reports concerning a patient may be assembled w before the clinic starts, so that there is no delay whi clerks search for missing information. Case-notes a of great value not only for the rich store of informatio they contain, but also as the hospital record of th identity of the patient who looks to it for advice. Th are not so much paper to be thrust into the pocket of a absent-minded leave-taking houseman, to be remove to a remote department unrecorded, to be left stack in an untidy filing department, to be pushed aside an then sought frantically while the clinic is in progres r should a patient seeking reassurance and advice his faith shattered by the hospital's incapacity to lace his case-paper.

---

[1] Bock, I. F., Gardner, F. V., Witts, L. J. *Brit. J. soc. Med.* 19 1, 197.

n appointments system will provide a clinician with ear picture of the day's work. A short conference allocation of cases, a glance at case-notes and nts, and a recapitulation afterwards of the cases h have been seen, will ensure continuity and coordition. Forewarned by the appointments system, the oner and members of other auxiliary departments cooperate over their cases with the medical staff. special clinics for teaching cases, the clinician s that in teaching he is not dislocating a carefully nged time-table, storing up patients to be rushed ugh at the end of the session or to be pushed on to er men. Student firms have a programme for the t and need not wait at unproductive clinics: and r a few words of explanation the patient may reciate the teaching importance of his case and kely secure the time for a second appointment for hing purposes.

he next step made easy by the medical records officer ception and registration. The medical records officer l consider in detail the approach of a patient to the pital. He will see that adequate directions are lable at all entrances, and that the patient quickly s his way to the registration desk, has a few words welcome and reassurance, and is comfortably seated. first registration the clerk will record the general ntity data required by every hospital department; d he will pass these on, thus saving endless repetition the patient. Often a receptionist escorts the patient the clinic, telling him whom he may expect to see.

After the clinic, the patient may need to have X-ray, hological, and follow-up appointments, which can be nged by direct inter-hospital communication at the patient appointment desk.

A reply may be made to the patient's doctor. The cords officer can either organise a pool of secretaries set up a team consisting of appointment and registran clerk, clinic receptionist, and medical secretary, to llow through the outpatient and inpatient work of ch firm.

The medical records officer will probably place the rdination of arrangements for admission and discharge the hands of an admission secretary, who will secure information required for an intelligent record on the aiting-list, tell the patient what he should do before mission, and acquaint him with the contents of the struction booklet which she will send to him before dmission. The admission secretary receives the bedtates each morning, and prepares the central record of noccupied beds. Under the direction of the firms who hold the medical responsibility for admission, she calls he patients who are to be admitted; she may inform heir doctors and will certainly send to each patient a etter accompanied by an informative booklet. She will arrange for an ambulance, inform the wards, the almoner, the chaplain, the caterer, and other departments, and have all records assembled before the patient's arrival.

The patient whose admission has been arranged will lready know the admission secretary's office, and will be expected. A time will have been arranged to receive him, to obtain any necessary legal consents, and receipts for valuables deposited, and conduct him to the ward with his case-papers assembled ready.

When a patient is to be discharged, the admission secretary will be forewarned. She will make sure that the arrangements for his return home or to convalescence are well made, arrange his follow-up appointment, explain instructions for his future welfare, have ready his ration book and valuables, and bid him farewell on behalf of the hospital, attending to his requests, complaints, or difficulties.

It is a pleasant and convenient arrangement for inquiries and calls from relatives and general practitioners to be dealt with by appointment by members of the hospital medical staff in a small room adjacent to the admission secretary's office where any patient may converse with his hospital doctor before discharge, and for calls of lesser importance regarding a patient's health to be dealt with by the admission secretary.

With sufficient secretarial help it should not be so difficult for the medical staff to find time to dictate concise medical summaries and letters to general practitioners, preceded by short notes on discharge.

In one conclusion I disagree with Dr. Lipscomb. In the absence of a medical records officer, no doubt an increase in registrars might ease the position; but what a waste of medical training! How would one ensure that these extra registrars had in their mind's eye the remedies Dr. Lipscomb envisages, and in their hearts the intention to see them through? Is it not better to appoint a specialist in coordination, properly trained, whose work is not simply a sideline born of sympathy? I am quite certain that a good medical records officer, having the goodwill of the medical staff and a well-ordered department, does successfully achieve the personal touch.

G. L. JOHN

St. Olave's Hospital,
London, S.E.16.

Medical Records Officer,
Bermondsey and Southwark Group
Hospital Management Committee.

SIR,—The article by Dr. Lipscomb and your leading article last week draw timely attention to a state of affairs of which all are conscious, which many attempt to improve, but which still makes for an unsatisfactory relationship between patient and hospital.

May I be allowed to point out, though, that so far as the teaching centres are concerned, one party appears to have been omitted from consideration—namely, the student. Despite the very junior position he occupies in the hospital hierarchy, the student is always impressed with the fact that he is a most important member of the team in getting to know the patient and giving reassurance from time to time.

Yet what does he find? He is well able to get acquainted with the patient on admission and conduct a most thorough examination. The registrar then teaches on the case as illustrative of a certain disorder. The chief later discourses upon it, uttering diagnostic wisdom and suggesting further tests and treatment. Thereafter the enthusiasm tends to wane. The houseman is largely responsible for further progress. Meanwhile the student, conscientious as he may be, finds it difficult to keep au fait with all that is happening. He observes from the bed-letter what treatment is being prescribed and deduces from the various reports a little further information about the pathology. The response to treatment he must judge for himself: and what bearing this will have on the outcome of the case and its final disposal he must surmise. Consequently when the patient inquires, as he soon does, what is going to happen next and when the stay in hospital will be terminated, the student, upon whom so much is said to depend, has perforce to give an evasive answer.

This difficulty can be solved, and in fact is overcome, particularly on certain firms. A weekly round of all patients can be conducted to discuss the present position and eventual result. Probably the best person to arrange this would be the houseman, but he is often recently qualified, and in any event is extremely busy. Once again the clinical assistant or registrar must shoulder this further burden, despite his present heavy load. There is no suggestion of aiding the lazy student, but he who would discuss with the patient must be able to speak with the authoritative voice of his chief.

London, W.2. ROY GOULDING.

CONCENTRATION OF DIPHTHERIA ANTITOXIN IN CORD BLOOD

SIR,—It seems that Dr. Wiener, who wrote last week, is not familiar with diphtheria-antitoxin titrations. May I suggest that he reads an article by Glenny and Llewellyn-Jones [1] which describes the methods used at the laboratories where the cord-blood samples were tested? Very few tests are necessary to obtain an accuracy of 10%. The final tests on these blood samples were made at 10% differences (as was made clear in our paper) and not 100% differences as Dr. Wiener evidently thinks.

All measurements of toxin and antitoxin in the titrations were made by a group of technicians with no knowledge of the nature of the samples they were handling. The readings of the reactions in the test animals were made by one of us who has had 20 years' experience of such work, and these reactions were a very small proportion of a daily average of about 500 read at a single sitting, without any reference either to former or to possibly expected results.

Final results were collected by a third person who applied a rigid formula to calculate the value of each sample. Thus a sample for which a test mixture at 10 units gave no reaction on each occasion, and a test mixture at 11 units always gave a reaction, was allotted a value of 10·5 units. If on one occasion the test for 11 units was recorded as a reduced reaction, or a very slight reaction was produced in a test for 10 units, the calculated value would be slightly different, but still between 10 and 11 units.

I have given an example of the simple procedure that we adopt in the interpretation of values, because some of your readers who do not know the extreme accuracy with which diphtheria antitoxin can be titrated might think that Dr. Wiener was writing with authority when he refers to a minimum error of 100%.

Wellcome Research Laboratories,
Beckenham, Kent.

MOLLIE BARR.

MALLEOLAR FRACTURES

SIR,—I cannot agree with Mr. Bonnin (Aug. 20) that we should doubt the histories given by patients with fractures of the external malleolus. I am far more sceptical of Thorndike's findings and of the results of cadaveric experiments.

Thorndike [2] diagnosed 415 cases of sprain of the ankle in college sportsmen over a period of six years. He claims to have located the sprain to a particular ligament in 317 cases. In 195 cases this was the anterior inferior tibiofibular ligament; in 61 the lateral collateral ligament; in 38 the medial collateral ligament; and in 23 the anterior tibio-astragaloid ligament. He does not subdivide the lateral collateral ligament and makes no comment on the distinction between sprains of its anterior fasciculus and sprains of the anterior inferior tibiofibular ligament. Furthermore, while claiming that any sprains especially involving the anterior inferior tibiofibular ligament will give a permanently weakened and widened mortise to the joint, he also claims that the average period of disability of all the ankle-sprains of the series was $8^1/_2$ days before return to full play in sports.

Mr. Bonnin refers to experimental work on the relation of the shape of the fracture-line to the mechanical stresses. But it does not follow that a particular fracture-line is not produced by a particular force simply because this has not been observed experimentally. For instance, Hönigschmied [3] had 21 cases of dorsiflexion strains in his experiments on the cadaver, but, for fairly obvious reasons, in none of these was an anterior marginal fracture of the tibia produced; yet such a fracture we reduce and fix in plantar flexion because we t it to be produced by dorsiflexion. He had 17 cases adduction strain, yet in none was there the so- first-degree adduction fracture. Dupuytren had results. Thus it does not seem unreasonable to the unbiassed history of an "unbadgered" patient.

Mr. Bonnin classified my groups 2 and 3 as "addu fractures, and my group 1 as external-rotation in Yet, as I previously pointed out, I have seen of the group 2 or 3 type associated with group-1 fr and apparently due to the same recent injury.

Lastly, Dupuytren did not contend that most of the external malleolus consequent on indirect vi and unassociated with other bony or complete l injury in the region of the ankle, are due to in strain. He thought that isolated fractures of the were a rarity, and he discourses on them as follows [4]:

> "It is at this spot therefore [$2^1/_2$ in. above the lo extremity of the fibula] that the least resistance is offe and that the causes capable of producing fracture act most advantage, as for instance in forced eversion of foot. Lastly, the fracture sometimes occurs below wh the ligaments connect the tibia and fibula together then it is rather a fracture of the malleolus and is consequ on inversion of the foot."

Dupuytren, incidentally, emphasised the importance muscle-pull in producing displacement in fractu dislocations of the ankle, in contradistinction to emphasis we now place on the causative violence. Perh we go too far in allocating one type of fracture-line one type of violence irrespective of the extent of associa lesions.

Scunthorpe.

DAVID THOMAS

PARA-AMINOSALICYLIC ACID IN TUBERCULOS

SIR,—Dr. Swanson's letter in your issue of July draws attention to the hypoprothrombinæmic effect *p*-aminosalicylic acid (P.A.S.) therapy in 5 out of patients with rheumatoid arthritis—an effect which points out is well known to occur during the exhibit of other salicylates.

This dicoumarol-like effect of other salicylates can prevented by simultaneous treatment with vitamin K one of its synthetic analogues; but when salicyl hæmorrhage has already taken place vitamin-K ther is unlikely to be effective.[5] It seems reasonable assume that in these respects P.A.S. resembles ot salicylates.

Meanwhile, some patients with tuberculosis are be treated with both P.A.S. and streptomycin. In th patients the possibility of hypoprothrombinæmia appe to be increased because of the bacteriostatic effect streptomycin on *Bact. coli* in the gut and the consequ decrease in the supply of vitamin K from this bacte source.

The problems of the mode of therapeutic action P.A.S. are still unsolved, though Le [illegible] bacteriostatic action to its rôle as a [illegible] of metabolites of the tubercle bacillus, these metabol possibly resembling salicylic and benzoic acids. At t stage, when trials of combined P.A.S. and streptomy are no doubt in progress, it may be worth draw attention to three considerations, not necessarily inco patible with Lehman's view. The first is that t vitamin K first used therapeutically in man was obtain from the pigment of the tubercle bacillus,[7] and it m therefore be assumed to play a part in the metaboli of the bacillus. The second is that the dicoumarol-li hypoprothrombinæmic action of salicylates on the li is possibly an anti-vitamin-K effect. The third, whi gests that prevention of the anticoagulant effect of a notherapeutic drug is not necessarily desirable, is tained in a statement by Prof. A. St. G. Huggett[8] the Biochemical Society, that the anticoagulation enzyme action of some trypanocidal dyes may have nalogy to their mechanism as trypanocidal agents.

hus in therapeutic trials with combined P.A.S. and ptomycin it appears worth considering that any oprothombinæmic effect observed may represent a ter hazard to the tubercle bacillus than to its host. ould then be possible to make a comparison between ients risking hypoprothrombinæmia but safeguarded serial prothrombin estimations, and those given a plement of vitamin K.

EMPLOYMENT OF ELDERLY PERSONS

IR,—The explanation of the conditions on which tional Insurance retirement pensions are paid, con- ied in your leading article of Sept. 10, is correct only spect of persons who reached minimum pensionable before July 5, 1948, and accordingly qualified for ir pensions under the old Contributory Pension Acts. e effect of the new National Insurance arrangements the willingness of elderly people to continue at work bviously a matter of considerable national importance, d I hope, therefore, that you will allow me to explain very different arrangements which apply to those ching pensionable age after July 5, 1948.

Assuming that the contribution conditions are fully isfied, a man may claim a retirement pension of 26s. m the age of 65 provided he has retired from regular ployment, inconsiderable occupations being ignored r women the qualifying age is 60). A man who does retire until after age 65 now goes on paying National urance contributions in exactly the same way as he before and remains entitled to sickness or unemploy- nt benefit at the same rate as pension, so that any nporary interruption of earnings after minimum nsion age provides no temptation to claim the retire- nt pension. For every 25 contributions paid in ployment after his 65th birthday the rate of pension yable from retirement is increased by 1*s*. a week. the man's wife has already reached 60 her notional nsion-rate (including that payable to her as a widow her husband dies before her) is also increased by 1*s*. every 25 contributions he pays. It is possible, erefore, for a man who goes on working until he is 70 acquire the right to a pension of 36*s*. a week for nself, and one of 26*s*. a week for his wife during his etime and 36*s*. thereafter. The increased rates of nsion payable in this way are, taking one case with other, actuarially broadly equivalent in value to the m of the pension forgone by postponing retirement d the contributions paid after minimum pension age. e arrangements therefore achieve the objective of the ggestion referred to in your leading article. From e 70 (65 for women) the increased rate of pension rned by postponed retirement is payable uncondi- onally whether work continues or not. As a reinforce- ent of the retirement condition, where pension is aimed on retirement before age 70 (or 65, as the case ay be), its payment up to that age is regulated by an rnings rule the effect of which is to reduce the pension aid for any week by 1*s*. for every 1*s*. of net earnings ver £1 in that week.

The general objective of the provisions of the new National Insurance Act is, of course, to encourage all those who can to continue in regular work wherever possible up to age 70 or even beyond. It may interest your readers to know that at the present time about two-thirds of the insured men reaching minimum pensionable age and nearly one-half of the insured women do not claim their retirement pensions, because they are continuing in regular work until later.

Ministry of National Insurance,
London, S.W.1.

Chief Press Officer.

VITAMIN E

SIR,—With regard to the letter from Professor Boyd and others (July 16), may I quote experimental data ? R. L. Holman[1] observed that, in dogs, vitamin E (3 mg. per kg. body-weight) had a significant protective action against hyperlipidic arteritis ; while Tusini[2] administered to rats altogether 5 mg. of ergotamine tartrate and found that the ensuing arterial spasm in the tail was, in over 90% of the animals, almost completely inhibited by giving 20 mg. of vitamin E daily. A synergistic action between vitamin E and vasodilators was also demonstrated, with very interesting therapeutic results.

Perhaps these results may lead to clearer judgment of the " extravagant claims " from the Shute Foundation.

Milan. V. FERRERO.

WHOOPING-COUGH TREATED WITH CHLOROMYCETIN

SIR,—Your leading article of Sept. 10 prompts me to report what may well be the first case of whooping-cough treated in this country by chloramphenicol ('Chloromycetin ').

My daughter, then aged $5\frac{1}{2}$ months, developed whooping-cough about the beginning of May this year and was in the early paroxysmal stage towards the middle of the month. Her older brother and sister had contracted the disease at the beginning of April and were by then well advanced in the paroxysmal stage. The infant was fully breast-fed and had been kept away from her brother and sister as much as possible, but of course some contact was inevitable.

Although her general condition was good, the attack was becoming fairly severe ; paroxysms became frequent, especially at nights, and during the two nights before treatment was started they occurred about every thirty minutes and often ended in vomiting. As good results with chloromycetin in whooping-cough had been reported from the U.S.A., and as the toxicity of the drug was supposed to be very low, I decided to try its effect while the baby was still in good condition and free from complications.

The drug had only come on the market during the previous week, and the dosage recommended was approximately that for typhoid fever—i.e., initially 50 mg. per kg. body-weight, followed by smaller amounts three-hourly. Chloromycetin being made up in 250 mg. capsules, I decided to give one capsule four-hourly as the baby was on four-hourly feeds. Her weight was then about 6–7 kg. Administration proved very difficult, since of course an infant cannot swallow these capsules. We tried to give the powder first in orange juice and then in expressed breast-milk. Both methods proved impossible because of the extreme bitterness of the drug ; the smallest taste of it made the baby retch and cry. We therefore decided to use an œsophageal catheter and found it easiest to introduce this through the mouth ; a good hearty cry assured us that it was in the right place. The first time we attempted this immediately after a feed, and the whole feed was brought up ; after that we gave it half an hour before each feed, when the stomach was presumably empty. This was successful and from that time on the baby retained the full amount of drug given and continued to feed normally. Because of these difficulties we continued to give 250 mg. four-hourly, up to a total of seven doses. Already after twelve hours the effect was noticeable, and the following night paroxysms were down to one every two or three hours. The drug was stopped as it was causing some colic and diarrhœa ; this subsided in twenty-four hours.

The effect on the whooping-cough was dramatic. After thirty-six hours the paroxysms stopped completely and the baby was obviously improving. The cough remained, and for many weeks the baby had occasional attacks of coughing, which, however, never gave rise to the slightest anxiety ;

she was never sick again, and she continued to make good progress. *A smaller dosage after the initial dose and a longer* course of treatment might possibly have averted the toxic symptoms and also abolished the cough.

There is no doubt that chloromycetin stopped what seemed to be developing into a severe case of whooping-cough. If this experience is confirmed by others—and I have already heard of one other case treated with good effect—whooping-cough should lose its dread. Its use will probably have to be confined to infants and severe cases at first because of the scarcity and high cost of the drug.

Hounslow, Middx. D. P. DEGENHARDT.

THE REGISTRAR'S SALARY

SIR,—As a junior registrar about to leave the hospital services, I should like to draw your attention to a plight which I feel must be by no means unique.

I *qualified just over four years ago*, served my houseman's apprenticeship, and studied for and gained the M.R.C.P. I entered the Services and served my two years. On release I approached an organisation mainly designed to "resettle" the medical ex-Serviceman, and was offered a year of subsidised cups of tea in a supernumerary capacity. Instead I sought, and took on, a junior registrarship, and in that position have been ruining my health for a net salary of £7 16*s.* 2*d.* weekly, after deduction of emoluments, tax, superannuation, &c. Of this salary 9% must be spent on the books and subscriptions necessary to the maintenance of my standards. I do not pretend to a car—I have only been qualified four years.

Now, if I take on a registrarship, my salary will rise to the giddy height of £775 per annum—i.e., about half the average G.P.'s income and under a quarter of the average dentist's. But then I become non-resident and must buy and keep up the car I have so long dreaded. As a responsible family man I have gone into my financial prospects and find that my net income, after the usual deductions at source, will be just under £600.

Well, I have remained shabby long enough—I am leaving for the comparative opulence of general practice, where incidentally I shall probably be able to afford an entire half-hour for my meals, and shall get decent food into the bargain. I shall be leaving with some relief; at least I shall be able to support my wife and child decently. But I shall bear a life-long grudge against the allegedly reformed system that drove me to do so.

Yet for all this I can blame no-one but myself and my peers for our cowardice and apathy in preserving a shabby dignity that baulks at organising to fight for our social rights—how else shall we get them?—and, above all, for our tacit condonation of a system that emphatically does not encourage "ability without means," but unopposedly exploits the competition for academic advancement and imposes on the less fortunate of us the crippling burden of chronic financial worry.

London, N.W.3. A. GEE.

*** During his training, and until he gained a sufficient reputation, the young specialist has always earned less than he could get by going into general practice; and men who married soon after qualification have almost always been obliged to abandon their intended specialty unless they had private means. The position has changed to the extent that hospital registrars, instead of receiving £300–400 or less, as before the war, are now on a scale rising from £670 to £1300, and on gaining staff appointments they immediately earn a minimum of £1400. The fact that this remuneration is lower than that generally obtainable (under quite different conditions) in general practice has to be weighed against the later advantages of the consultant's life, which include the possibility of a much higher income than that of the practitioner. We must regret, on all grounds, that any young doctor should feel obliged to enter general pr when his heart is elsewhere; but we would point o our correspondent that under the "allegedly refo system" he has at least an opportunity of continuin training, whereas formerly he would have had none —Ed

THE DOCTOR'S PROFESSION

SIR,—In the third article of this excellent serie following sentence occurs on p. 338 (Aug. 20): "Alt he is no longer normally required to take the Hippoc Oath, the doctor is bound to respect human life i its forms." If this basic obligation is to be met profession must keep clear of bacteriological warfar other military work. It seems necessary that wh medically qualified person is engaged on such wor should recognisably separate himself from the profe in the way that a doctor does who changes fro medical to a combatant rôle in the Forces. If th not done the public will be alarmed and a Governm might come which would demand destructive wor part of the profession's duty. I suggest that do who do such work should be, for the time, seconded the profession with the right to return to it when have finished destructive work.

London, W.1. J. M. ALSTO

RESEARCH

SIR,—With regard to the reference in your lea article of Sept. 3 to the use of endowment funds research purposes, I would like to inform you that board of governors at this hospital decided, sh after the introduction of the National Health Ser to earmark for clinical research at least two-third the annual income from endowment-fund investmen

Middlesex Hospital,

Chairman, Medical Committ

POLIOMYELITIS AND TONSILLECTOMY

SIR,—Acute anterior poliomyelitis following sho after tonsillectomy may be due to the entry of infec through the wounds in the throat.

But there is a wider problem. Some evidence sh that the tonsils and other subepithelial lymph-gl can confer some degree of immunity against cer infectious diseases even when the disease itself is contracted; and the mechanism by which they c do this has been demonstrated. Whether faucial nasopharyngeal tonsils function in this way aga poliomyelitis where the disease is endemic is a ques ripe for investigation.

Last year Glover[1] published a valuable collectio evidence on the relation of tonsillectomy to poliomye But much of the work refers to tonsillectomy *rece* performed, where infection through the open wou is a possibility. One would like more figures on incidence and severity of the disease in patients have had tonsillectomy performed more than six mon previously.

The removal of tonsils and adenoids leaves for a t three open wounds through which infection can enter body. It may also be expected sometimes to cause almost unnoticeable attack that may confer immun It is therefore desirable to know not only whet and when tonsils and adenoids have been remov but also whether the disease was prevalent locally at time of removal.

Every doctor who has a case of poliomyelitis mi make a point of recording these data. The compil of statistics from such data and the drawing of conclusi from them will be a complicated task requiring mu care.

Bromley, Kent. KENELM H. DIGBY

WHY I SHOULD MOVE

R,—Few people realise that a grading of senior ital medical officer or lower carries with it no native but to seek another appointment. For me means selling up my home and moving my family myself away from friends, colleagues, and the ict of our choice. For many it entails also moving ren away from selected schools and breaking up a established private practice.

sultants not threatened by such an impasse ely can realise the magnitude of this disaster. The ster has promised us that we should not be forced ove. The appeals committees lightly take it upon elves to compel it: appeals committees of much ised composition who prefer to remain unknown. e to interview applicants, and spurn local advice.

hy have so few consultants protested against the rice of this procedure, an injustice they must all seen operative among their immediate colleagues? hopes it is largely because they fail to realise the cations of this final assessment. Many point to statement "I should add that this grading may be ewed during the next few years." Let them note it contains no promise to review, and that the r hospital medical officer will have then no further ts to consultant status than he has today and far chance of moving. No, he must move today. Old young have this one solution. Their turn will not e by waiting.

ny consultants still believe that there will be a ter appeal. This can only come if they stand fairly squarely behind their less fortunate colleagues. commendation for adequate appeals machinery to et up should be sent from every specialist individually is college and from every group medical advisory mittee to the regional medical advisory committee, regional and central consultants' and specialists' mittee, and all other interested bodies.

hester, Sussex.   JOHN D. WHITESIDE.

PREVENTION OF BURNS

R,—Why is there always such a time-lag between announcement of scientific advances and their prac- application? In the sphere of medicine, is it use practitioners are not adequately informed about ress, or is it because the profession is unable to ess its views sufficiently unitedly and effectively in places where appropriate action can be taken to fit the community at large?

alarial control has been possible for a long time, at t in circumscribed areas; but often in British onies the immediate cost has prevented action, fficient account being taken of the likely ultimate efit to the economy of the territory. (The Panama al zone provides a striking instance of this, though ewhat artificial conditions exist here.) As far as I aware only the United Fruit Company has made a parison between the direct costs of effective anti- arial measures and the ultimate financial advantages n them; however, the work initiated by Dr. Cheverton ughout Cyprus should within the next few years vide further data.

The article by Dr. and Mrs. Colebrook in your issue of y 30, on the prevention of burns, aptly reviews a ation allowed to develop under our noses and partly direct violation of the law of the land. Recent erience has emphasised that legislation opposed by e public tends to become ineffective. The Colebrooks tly appeal for propaganda to remedy the public's ning ignorance of the issue of life and death involved the prevention of thermal burns. Irrespective of such propaganda, the results of which are notoriously difficult to assess, much could be done by simple legislation, on the lines indicated by Dr. and Mrs. Colebrook, which probably would be of greater direct benefit to the community than much of the legislation occupying Parliamentary time at present.

London, W.1.   W. R. THROWER.

SIR,—Mr. Moncrieff's summary (Sept. 10) of the fire-proofing problem from the point of view of the textile chemist will have been appreciated by many readers who are concerned about the risk of burns associated with highly inflammable clothing.

It would be improper for me to comment upon the purely technical points he makes, but perhaps I may legitimately refer to an assertion by him which has more to do with human nature than with textiles. He says: "There is no easy solution to the problem of making cotton, wool-cotton mixtures, or viscose rayon fabrics non-inflammable: if there had been it would doubtless have been adopted."

Is there really no room for doubt about this? If Mr. Moncrieff has read the evidence given before the *Home Office committee (the evidence is much more* important than the committee's final report) which in 1910 was considering the dangers of flannelette and the merits of a virtually non-inflammable form of that material impregnated with stannic oxide—which was at that time on the market—he cannot have failed to notice that the witnesses representing the flannelette industry, other than the one firm concerned in the production of the fire-proofed variety, were quite openly and strongly opposed to the introduction of the safe material.

The nature of their opposition is important. They did not maintain that the "handle" of the safe material had been adversely affected; nor that its wearing capacity was diminished (the only evidence of this was a single letter, while on the other hand the testing house of the Manchester Chamber of Commerce reported the wearing capacity of the proofed material substantially increased); nor did they oppose the proofed material because it failed to maintain its non-inflammability after washing (that was clearly disposed of by the many experiments of the Government chemists and of the British Fire Prevention Committee).

The flannelette makers opposed the introduction of the proofed material chiefly on two grounds: (1) that the price to the retail buyer was higher than that of the untreated materials, and that this was not in the public interest; and (2) that it was unfair to the makers of flannelette to single out this material when other "cottons" were just as inflammable. The sales of flannelette had, they said, already been seriously affected, and the future of a number of firms making the material might become precarious if the demand for this safe fabric—made under patent by one firm—became established.

It is difficult after reading all the evidence given to resist the conclusion that the stannic-oxide fire-proofing process, as used in 1910, had produced a safe flannelette which was, if not completely, at least almost completely satisfactory; and that its adoption was "killed" chiefly by the opposition of the other flannelette manufacturers who—being only human—were more concerned about the success of their business than about a rather uncertain number of accidents to children they had never seen. I suggest that if these manufacturers had got together in 1910, and had agreed to settle the difficulty over patent rights and to improve the fire-proofing process if it was not already perfect, we should long ago have had children and women clothed in non-inflammable materials, with the result that thousands of deaths and of ruined lives would have been avoided.

I am aware that a considerable amount of research has been carried on since 1910 with the aim of producing fire-proofed fabrics, for military and industrial purposes, but I understand that it has usually had an objective rather different from that in question here—namely, to produce a fabric which was weather-proof as well as fire-proof. May it not be that the stannic-oxide method was in fact reasonably satisfactory for the limited objective of safeguarding children's clothing, although it would have been useless for weather-proofing?

In view of the urgency of this matter, now that we have sure knowledge about the frequency of these tragic accidents (about five a day in England and Wales—i.e., about 1800 a year—of which more than 25% are fatal) would it not be well to settle once and for all the merits or demerits of the stannic-oxide-proofed material by preparing a few dozen yards of it and submitting it for careful examination by a panel of people who have no financial interest in it? If the material proves unsatisfactory, then let us decide whether, in the light of modern knowledge about fire-proofing, the availability of raw materials, and other considerations such as cost, it is best to pursue the search for better methods of fire-proofing cotton fabrics or to focus attention on alternative *materials* such as woollens, 'Nylon,' and viscose rayons.

While the search for the ideal material is going on (it may take some years) I submit that it would be better to offer the public at least the opportunity to buy some relatively safe substitutes for the manifestly unsafe materials now on the market.

Finally, I respectfully suggest that it would be valuable if the evidence as well as the final report of the 1908–10 Home Office committee could be republished. At present it is available only in very few libraries (the Royal Society of Medicine has one copy), and the evidence is presented in an extraordinarily inconvenient form, being interspersed with quite irrelevant matter about the law relating to coroners. (Report of the Departmental Committee on Coroners. H.M. Stationery Office. 1910.)

Farnham Royal,
Bucks.

LEONARD COLEBROOK
Formerly Director, M.R.C. Burns Unit.

FOREIGN BODY IN THE ABDOMEN

SIR,—The case reported by Mr. Travers in your issue of Sept. 10 reminds me of an even more interesting case.

A married woman of 51 reported with a history of lower abdominal pain starting in the right iliac fossa five days previously. She had noticed a subumbilical swelling over the same period. There was no constitutional disturbance apart from a poor appetite. Her doctor diagnosed an ovarian cyst.

The patient appeared well in herself and had walked up to the outpatient department. A slightly tender spherical swelling, some 3 in. in diameter, was present below the umbilicus. She was too stout for accurate diagnosis.

A few hours after admission a definite blush of the overlying skin was observed, and subcutaneous abscess was diagnosed. After incision and evacuation of the pus, digital exploration revealed a fish-bone-like object, some $^3/_4$ in. long, sharp at one end, lying on the rectus sheath. Penicillin injections were given in view of the possibility of erysipeloid. Convalescence was uneventful, the abscess cavity being clean and ready for secondary suture in ten days.

On being shown the offending object, the patient exclaimed: "Ah, that's an eel bone; we have eels every Sunday."

In this case, therefore, the bone had not only escaped from the bowel and traversed the peritoneal cavity but had perforated the whole thickness of the abdominal wall before calling attention to itself. Enterococci and *Bact. coli* were grown from the pus.

Mile End Hospital, London, E.1. S. WILLSON HOLMES.

MEMORIAL TO C. J. BOND

SIR,—In their letter last week, Dr. Walker Mr. Spriggs, writing of the fund which is being in Leicester to provide a memorial to the late C. J. make no reference to what was undoubtedly one great interests in the later years of his life—the qu of voluntary euthanasia.

He took a leading part in the formation of the Vol Euthanasia Legalisation Society, and was the chairman of its executive committee—a position until his death. It was at his personal invitatio the late Lord Moynihan became the first p the new society, and doubtless it was largely due great prestige attaching to Bond's and M names that the society made the rapid progress in securing the adherence and support of so many distinguished members of the medical profession.

No review of Bond's life and work would be without a reference to this aspect; and possibly years to come he will be chiefly remembered and for the great part he played in the initiation o reform.

C. KILLICK MILLARD
Hon. Secretary,
Leicester. Voluntary Euthanasia Legalisation Soc

Public Health

Poliomyelitis

IN the week ended Sept. 10 notifications in E and Wales were: poliomyelitis 284 (280), encephalitis 22 (19). Figures for the previous we shown in parentheses.

Multiple cases (poliomyelitis and polioencep together) were reported from the following cou London 31 (43), Berkshire 4 (5), Chester 6 (3), Co 3 (5), Derby 2 (2), Devon 5 (7), Dorset 5 (2), Du 7 (8), Essex 16 (21), Gloucester 10 (13), Hereford Hertford 5 (3), Kent 9 (10), Lancaster 38 (28), Lei 7 (11), Lincs, Kesteven 2 (2), Middlesex 19 (18), umberland 8 (10), Nottingham 16 (6), Oxford Soke of Peterborough 5 (0), Somerset 3 (9), Southa 15 (10), Stafford 4 (3), Surrey 9 (7), Sussex, East Warwick 10 (8), Isle of Wight 2 (0), Wiltshire Yorks, *East Riding* 3 (1), Yorks, West Riding 25 Glamorgan 7 (5), Monmouth 2 (1).

Notifications in England and Wales in the sponding week of 1947 (week ended Sept. 6) poliomyelitis 662, polioencephalitis 46. These we highest weekly figures recorded in that year.

Typhus Fever in a Ship

S.S. *Monte Montjuich* arrived in the Port of L from Melilla (North Africa) on Aug. 17. Two me of the crew were admitted to hospital with susp enteric fever on Aug. 22, and a third on Aug. 25. vessel then sailed for Newport (Monmouth) and a on Aug. 28, when a fourth member of the crew wa to hospital with a similar diagnosis. Two f cases occurred on Sept. 6, while another member o crew was under treatment in hospital for midd disease.

All sanitary measures were taken on board, a addition fumigation was carried out in Newport, 803 rats were destroyed. The ship sailed for Ro Argentina, on Sept. 7.

The laboratory tests on these cases proved ne until Sept. 2, when Widal tests on the first two pa suggested infection with *Salmonella paratyphi-B.* Sept. 7, however, a repetition of the Weil-Felix on serum from the seven patients proved positiv typhus infections, but further investigation on boar not possible as the ship had sailed that morning. the patients are recovering; the attack was mi every case. There was no evidence of lice infesta

It is not yet apparent whether the infection w murine or louse-borne origin. Spread in the British is not expected.

Obituary

AUGUST KROGH

the death in Copenhagen of August Krogh, news ich reached this country last week, physiology has n outstanding figure. He was born in 1874, and as ld showed a lively interest in small animals and te—an indication of that spirit of inquiry which to direct all his future work. He took his degree in gy at the University of Copenhagen in 1899, but he already been working as a student in Christian 's physiological laboratory and he now became his tant. Some years later he was appointed to the rsity chair of zoophysiology. From he learnt much about the analysis es, and this stimulated his interest ethods of accurate investigation quantitative analysis which he was on to develop in so masterly a way. etter illustration of this can be d than in a paper published in on the possible formation and ation of free nitrogen by the al, which, in disproving this hypo- s, is a model of technical skill and al reasoning. The same elegance chnique, aided by his knowledge ology, is shown in his physio- al researches on insects, to which turned at intervals during his e life. But he will be more widely mbered for the great contribution h he made to the physiology of higher animals and man in that field embraced in the term spiration."

ith his wife he spent the summer in Greenland studying the diet metabolism of Eskimos, who, owing e rigour of the climate, are for long periods obliged bsist almost entirely on fish, seal meat, and fat. e of the difficulties of an improvised laboratory he able to throw much light on this nutritional problem a study of the respiratory exchange and nitro- us metabolism. Ten years later, in another metabolic y of the respiratory exchange, which exemplifies the eme care which he devoted to the planning and uct of his experimental work, he showed that fat ed as a source of muscular energy somewhat less ently than carbohydrate.

a series of papers published in 1910 he reached the lusion that the passage of gases between the blood air in the lungs can be adequately explained by ple gaseous diffusion, without recourse to the theory active secretion of gases which had been advocated others, basing his views in large part on the results ined by new instruments which he had designed for mining the gas tensions in the blood. In the following s he was to devote much attention to the problem of regulation of breathing, and he contributed numerous ers on this subject and on the physiology of muscular rcise.

In 1912 he introduced a surprisingly simple technique determining the blood-flow through the lungs of man. ich depended on the inhalation of nitrous oxide and the asurement of the amount of this gas carried away from e lungs in solution in the blood. With the substitution acetylene for nitrous oxide this method has with slight modification been used by many investigators studying the cardiac output during rest and muscular ercise.

It was while writing a monograph on the Respiratory xchange of Animals and Man (London, 1916) that rogh's attention was drawn to the capillary circulation. uring severe exercise the oxygen consumption of the tive muscles may increase to some twentyfold the resting gure, and it seemed to him that the requisite variation n oxygen supply to these muscles could not be satis- actorily explained by the assumption that the blood asses through a fixed system of capillaries with a corre- ponding variation in velocity, but that the condition ould be better met if some capillaries only were functional during rest and that capillaries which were p viously closed could open up to allow the passage a larger flow of blood as occasion demanded. This le him to his detailed studies of capillary circulation and to the theory of the functional alteration of the capillary tone, a conception akin to that reached by Dale and Richards in this country in 1918 by a different line of argument in their investigation of the effects of histamine. A full account of his researches in this field was given by Krogh in his Silliman lectures delivered at Yale University and published under the title The Anatomy and Physiology of Capillaries in 1922 (2nd ed. 1929). In 1920 the great value of his researches was recognised by the award of a Nobel prize.

[C. Ess

After the discovery of insulin Krogh was largely responsible for its introduction into Denmark and for arranging for its manufacture in that country. In his later years he became interested in the osmotic regulation in aquatic animals which formed the title of a monograph published in 1939, and in the passage of ions through the surface of living cells which was the subject of his Croonian lecture to the Royal Society, of which he had been elected a Foreign Member in 1937. Although he retired from his university chair in 1945, he continued working until the end, and only last summer took part in a conference in Cambridge held in memory of Sir Joseph Barcroft.

To mention but briefly some of the most prominent fields in which Krogh worked gives, however, no adequate impression of his ability. No-one who reads his scientific publications can fail to admire his technical skill and versatility, and to appreciate the amount of thought which he devoted to all his experimental investigations. He himself has claimed that he owed much to his natural gift for visualising even complicated apparatus and the details of its working as well as the physiological processes which might be involved, for this enabled him to develop hypotheses which could then be put to the test of experiment. Apart from his own contributions to physiology his influence and inspiration are evident in the work of all those who were privileged to be associated with him.

Critical of others, but without malice, he was critical, too, of himself. His shyness concealed a real gift for friendship, and those who knew him well could appreciate his personal charm and quiet humour. It was only natural that he should have early in his career formed a lasting friendship with J. S. Haldane and Joseph Barcroft, whose interests lay in the same sphere as his own; but very many others both in this country and in America could claim his friendship too. So much of his work was devoted to the subject of human physiology that he had a very clear conception of the significance of this to medicine: indeed he regarded human physiology as the basic science for the profession of medicine, and he was much in favour of coöperation between the teachers of physiology and the teachers of medicine and surgery in the medical schools.

C. G. D.

HENRY HENDERSON MOLL

M.D. LEEDS, M.D. ROME, F.R.C.P.

Dr. H. H. Moll, senior physician to the General Infirmary at Leeds, died suddenly in the Brotherton wing of the hospital on Sept. 8.

Of Scottish and Italian descent, he was born in Italy in 1896 and received his early education in Milan. He proceeded to the University of Pavia and later to Rome for the completion of his clinical studies, graduating M.D. at the latter university in 1918. In 1920 he visited England and studied for two years at St. Bartholomew's Hospital, London.

Family ties in Yorkshire led him to apply for the post of resident medical officer at the General Infirmary. His successful tenure of this key appointment opened the way to consulting practice; and in 1924 he obtained the M.R.C.P., followed by the degrees of M.B. and M.D. of the University of Leeds. In 1932 he was appointed an assistant physician to the General Infirmary at Leeds and hon. physician to the Leeds Public Dispensary and Hospital.

During the period of postgraduate study in London, he became interested in diseases of the chest, and whilst holding the appointment of medical tutor in the University of Leeds he established a large clinic for the study of asthma. This work, which was coördinated with the national investigation, retained his active interest. Shortly before his death he was planning for the reopening of the clinic, closed on account of the war, and for the establishment of an inpatient centre at Pinderfields Hospital for the study of asthma, allergic diseases, and infective conditions of the chest. Of his published work, perhaps the best known is that on bronchiectasis which appeared in the *Quarterly Journal of Medicine*. He was elected F.R.C.P. in 1938, shortly after his appointment to the full staff of the General Infirmary, where last year he became senior physician.

He married, in 1935, Francesca Teresa Soldi, the artist, and is survived by his wife and four children.

A man of wide reading and intensely interested in the advancement of medical knowledge, his sudden death is a loss to the profession. R. E. T.

ANNIE McCALL

M.D. BERNE

Dr. Annie McCall, founder of the Clapham Maternity Hospital, London, was a very remarkable woman and a most forceful character. She studied in the early days at the London School of Medicine for Women, taking her M.D. at Berne in 1885. She had her obstetrical training mainly in Vienna and she devoted nearly all her life to the practice of this branch of medicine and to the training of women medical students and nurses in practical midwifery.

In 1889 she founded the Clapham Maternity Hospital by her own efforts and with the help of those friends who were interested in the advancement of women's education. From there many doctors and nurses went abroad to the mission fields, and women also came from overseas to be trained as midwives. Throughout its long history the hospital was never allowed to be in debt—owing to the personal supervision and administrative ability of Dr. McCall herself. She was the supreme head, and no details of its management were too small for her.

She practised conservative midwifery, allowing as little interference as possible with the course of labour. Her results were remarkable, and puerperal sepsis was of the rarest occurrence in the hospital. Masterly inactivity was the watchword and she enforced the constant supervision of the patients by those who were in attendance. As a consequence, the maternal mortality and stillbirth rates were remarkably low. The only interference permitted was the application of obstetric forceps when approved by Dr. McCall herself or her senior assistant. She ruled her staff with a firm hand, and many women doctors and nurses who were trained by her learned to appreciate the value of conservative methods. Caring little for the opinion of others, she had her own code of conduct. She was a law unto herself, and insisted on maintaining obedience to her direction among her staff. She was a great believer in the value of fresh air and open windows, even when a gale might blow papers about, and in addition to her obstetric work she was a pioneer in the treatment of pulmonary tuberculosis, establishing a small sanatorium at Rudgwick, in Sussex, for open-air treatment. She lived in Clapham Road, where she housed medical students and enjoyed occasional relaxation in her beautiful garden.

Dr. McCall was a rigid advocate of temperance, and never allowed alcohol to be used in the treatment of patients; at meetings she sometimes spoke with great conviction on the subject. She had much sympathy for the plight of unmarried mothers and their inability to find accommodation for their confinements other than at the workhouse infirmary.

At the Clapham Maternity Hospital she was helped by her cousin, Miss Ritchie—a woman of great culture and boundless sympathy and gentleness, who was much beloved and who often softened forcible directorship of Dr. McCall. Both of women must be remembered as having done for obstetrics, especially during a period whe branch of practice was looked upon as beneath the of the physician and surgeon—a period, now past, it was thought bad form in social life to mention nancy or childbirth. One was always impressed their earnest endeavour to make the world a better for mothers. Dr. McCall died at Rudgwick on S aged almost 90. A. I

REGINALD ERNEST BICKERTON

D.S.O., T.D., M.B. VICT.

Colonel Bickerton, ophthalmic surgeon to the Se Hospital and consulting ophthalmic surgeon t Evelina, the Royal Waterloo, and other London hos died on Sept. 13 at his home in Portland Place, wh had practised for many years. The son of T Bickerton, F.R.C.S.E., of Liverpool, he was bo Dec. 16, 1870, and after [illegible] sc Durham went to the [illegible] ol, hamsted. On leaving school he went to live wi half-brother, Mr. T. H. Bickerton, F.R.C.S., in Live and began his medical training at University C Liverpool, qualifying in 1895. Having held v house-appointments at the Royal Infirmary, he the many other Liverpool medical graduates, went to America as a ship's doctor. On his return he seriously to ophthalmology, in which he was a interested, and worked in Vienna, Berlin, and before coming to London to gain further experie Moorfields and elsewhere. He early secured an ho appointment at the Seamen's Hospital, and followed. Meanwhile he had become an active sup of the Territorial movement. He was a c R.A.M.C. (T.) by 1912, and was mobilised on A 1914, to serve successively in France, Egypt, Sal and Turkey. He commanded a field ambulance 1916, was ophthalmic specialist to the British Sa Force, and was acting A.D.M.S. to the Army of the Sea. He was twice mentioned in despatches, an awarded the D.S.O.; from 1927 to 1932 he was surgeon to the King.

Outside ophthalmology Colonel Bickerton had interests. In youth he was a keen yachtsman, a skill with the banjo made him a popular figure at h and other gatherings. When he came to Lond took up motoring, at that time in its earlier p Throughout the late war he remained in active p in London, and though his health became indiffer continued almost to the end of his life to see a his old patients. Many will remember him f kindliness, gentleness, and courtesy. He was cha of the Royal School for the Blind at Leatherhead.

He married Constance Livesey, who survives hi a son and a daughter.

Births, Marriages, and Deaths

BIRTHS

AIREY.—On Sept. 12, the wife of Dr. G. O. Airey—a son.

LEECH.—On Sept. 12, at Axminster, the wife of Dr. K. W. —a son.

PHIBBS.—On Sept. 10, the wife of Dr. P. A. T. Phibbs—a da

ROTHWELL.—On Sept. 8, at Bury, Lancs, the wife of Dr. Rothwell—a daughter.

WAUGH.—On Sept. 16, in London, the wife of Mr. William W F.R.C.S.—a daughter.

MARRIAGES

FOWLER—KENNEDY.—On Sept. 10, in Birmingham, Frank Fowler, O.B.E., M.B., to Josephine Kennedy.

THOMSON—CULLING.—On Sept. 12, at Bushey, Herts, Wy Thomson, M.D., to Mary Winifred Culling.

DEATHS

BICKERTON.—On Sept. 13, in London, Reginald Ernest Bick D.S.O., M.B. Manc., colonel, R.A.M.C.(T.).

ELWORTHY.—On Sept. 11, in London, Reginald Robert Elw O.B.E., M.D., aged 66.

JENKINS.—On Sept. 15, Charles Evans Jenkins, M.R.C.S.

KINLOCH.—On Sept. 14, at Shoreham-by-Sea, William An Kinloch, M.B. Aberd., aged 76.

MANNINGTON.—On Sept. 12, at Hastings, Frank Mannin F.R.C.S., aged 75.

SMITH.—On Sept. 16, Harry Smith, M.R.C.S., D.P.H.

Notes and News

RELIEF OF NAUSEA IN PREGNANCY

SEA occurs in about 50% of pregnancies, and in about vomiting ensues. A preliminary report [1] suggests that nt remedy for these symptoms has been found in mamine' (β-dimethylaminoethyl benzohydril ether otheophyllinate), which has already yielded promising , in the treatment of seasickness.[2] Of 43 pregnant i who had had nausea and vomiting for 4–6 weeks, .) were completely relieved three hours after dramamine lministered; in the remaining 12 (28%) the drug had ct. In 10 of the cases successfully treated, the replace- of dramamine by a placebo was followed by relapse. e symptoms were promptly dispelled when dramamine ain administered. Each patient received 100 mg. times daily; but in 7 cases the dose was reduced to . three times daily because of minor side effects— ss and vague subjective muscle tremors.

HYDROTHERAPY ASSISTANTS

Chartered Society of Physiotherapy intends to assume sibility for training and registering those who carry out, st in carrying out, certain hydrotherapeutic treatments. andidates beginning at the age of 16 the training will bly last two years, while for those beginning at a later will probably last one year. A supplementary register assistants is to be opened: part 1, to be established ar, will include those who have already completed five satisfactory experience. In addition a provisional list opened, and will contain the names of those who have ted two years' satisfactory experience; they may for transfer to the supplementary register on completing ars' experience. Hydrotherapy assistants admitted to pplementary register (part 1) or to the provisional list permitted to carry out spray massage, douche massage, ny form of massage, movement, and manipulations water; but they may work only under the supervision hartered physiotherapist or a doctor. Part 2 of the mentary register, to be opened in October, 1951, will n the names of those who have completed the prescribed of training and have passed the society's examinations.

CHILDREN'S FEET

many years school medical officers have been raged to examine children's feet; for deformities ed early can be successfully treated, and chronic infec- an be cleared up before they become resistant. Many doctors take this task seriously, and require the en to come to the examination with their stockings off; seems that in many cases children continue to wear ngs during inspection. The Foot Health Education u has lately published a pamphlet [3] prepared by a al committee, which sets out clearly some suggestions may help school doctors to spot early the deformities an orthopædic surgeon can readily correct.

seems that at present quite unimportant degrees of sed flat-foot are the only conditions commonly referred; here is evidence that many of the foot abnormalities give trouble during (but seldom before) middle-age in childhood. In one group of children studied the rtion of those with hallux valgus rose from 5% in the r-olds to 52% in the 11–15 age-group. Socks and are the deforming agents of the growing foot, but it is ntil a child reaches the age of 8–10 that the distortion e great toe and its metatarsal can be recognised. At stage it can readily be corrected in an orthopædic depart- —but only if it is referred there. Other deformities are mportant, and most of them can be corrected only by tion. Claw and hammer toes are best tackled between ges of 10 and 16. An overlapping 5th toe needs earlier ction.

e pamphlet carries advice on the measuring of shoes, t of stockings, and the significance of postural defects; roughly practical addition is a sample of a foot-inspection record-sheet, copies of which can be ordered in bulk from the bureau. As the writers say, we have much to learn about the treatment of foot troubles; but we shall never learn until sufficient cases have been under observation. The pamphlet is to be discussed at a conference at Caxton Hall, London, on Friday, Sept. 30.

COLOURING THE OUTLOOK

THERE is something about the gluttonous way beginners at painting appropriate colour which is very heartening: it can be enjoyed to the full in the second Exhibition of Children's Art, arranged by the *Sunday Dispatch*, now on view at the Royal Institute Galleries, Piccadilly.

Patients from the mental treatment centre of Hill End Hospital are also holding their second annual exhibition, which may be seen until Oct. 1 at Foyle's Art Gallery, Charing Cross Road. Their work, however, is not as staggering as that of the children—nor indeed as that of their forerunners of last year. These pictures are less wildly personal, more consciously composed. The catalogue notes that most of them are by new patients: which seems to suggest either that the new exhibitors have better coördination of hand and eye or less emotional disturbance, than their predecessors; or else that Mr. N. C. Colquhoun, in charge of the painting class, has unconsciously allowed his zeal as a teacher to master his scientific detachment. Nevertheless, for some of the exhibitors mood was overwhelming. Two pictures—"A Day" and "A Week"—painted in columns bearing symbols of the patient's experiences, almost hour by hour, are heavily weighted with anxiety and depression. In a terrifying fantasy of "Flight through Space," by another patient, a vast yellow rocket shoots between planets. Many patients have painted nostalgic scenes of peace and safety (among these, the lighthouse with its swirling green seas is outstanding); and some have painted desolation. The most remarkable picture, judged as a painting, is "Autumn Tapestry," where a patchwork jumble of colours—rocks, clouds, great leaves, and wooden beams—resolves itself into a boat passing through a canal lock in a wooded country.

From the point of view of the clinician visiting this exhibition it would be a help to know, where several pictures are submitted, in what order they were painted.

University of Sheffield

The address at the opening of the new session of the medical school will be delivered in the Firth Hall on Friday, Oct. 21, at 5 P.M., by Mr. E. F. Finch, who is to speak on the Evolution of Medical Education.

University of Birmingham

The opening ceremony of the new session of the medical school will take place in the nurses' recreation hall, Nuffield House, Queen Elizabeth Hospital, on Tuesday, Oct. 4, at 3 P.M., when the Archbishop of Canterbury will deliver an address.

Royal Faculty of Physicians and Surgeons of Glasgow

At a meeting of the faculty on Sept. 5, with Dr. W. R. Snodgrass, the president, in the chair, the following were admitted to the fellowship:

Qua Physician.—John Barclay Barr, Allan John MacKenzie Campbell, Robert Fife, William Morton Fyfe, Somesh Chandra Ghosh, James Tudhope Hutchison, Arthur Colville Kennedy, Andrew Wilson Lees, Roderick Frank Maggs, Andrew Greig Melrose, Germano Antonio Vieira Ribeiro, Irene Parker Rowlands, Ram Sevak Singh, Thomas James Thomson, George Frederick Walker.

Qua Surgeon.—Abd El Hamid Bayoumi, Alastair Kingsley Brown, Henry McCraig Carson, Gordon Alexander Clark, Hugh Bush Crum, Frederick George Day, John Stewart Farrell Hutchison, John Lockie, Ian Reay McCaul, John Reid MacIntyre, Alexander Mellick, Pierre Stuart Olivier, Frank Riggall, Pyare Lal Rishi, Dudley James Toomey, William Francis Toomey, Harold Bernard Watson.

Rheumatism Exhibition and Conference

An exhibition organised by the British Rheumatic Association is to be opened at Chenil Galleries, King's Road, London, S.W.3, on Tuesday, Sept. 27, and will remain open until Friday, Sept. 30. The purpose is to illustrate the activities, aids, and appliances related to the treatment, aftercare, and training and employment of rheumatic patients. A two-day conference, to be held in Chelsea Town Hall, will begin on Wednesday, Sept. 28, at 2.30 P.M., with an address by Dr. W. S. C. Copeman on Modern Views on the Treatment of Rheumatoid Arthritis: at 5 P.M. Dr. W. S. Tegner will speak on the Care of the Rural Patient.

ot Inspection in Childhood and Adolescence. Obtainable rom the bureau, 121, Ebury Street, London, S.W.1. Pp. 8. 1s.

Charing Cross Hospital Medical School

The inaugural address of the new session will be delivered by Sir Norman Birkett at the hospital on Thursday, Oct. 6, at 4 P.M.

Board of Control

Miss Isabel Wilson, F.R.C.P., now a commissioner of the Board of Control, has been appointed a senior commissioner and member of the board, in succession to Miss Ruth Darwin.

Central Council for Health Education

Dr. L. J. H. Burton has been appointed deputy, and Dr. Anne F. Burgess assistant, to Dr. Robert Sutherland, medical adviser and secretary of the council.

Blood Donors

In England and Wales during the second quarter of this year gifts of blood to the National Blood Transfusion Service totalled 110,993—12,938 more than in the same quarter last year. New donors in the quarter numbered 36,847—the biggest response since the war—bringing the total strength of donor panels to 382,382. Hospitals are now using over forty times as much blood as before the war; and the demand is still rising. To provide for these future needs, over 190,000 more donors are wanted.

Travelling Expenses of Hospital Visitors

The Minister of Health has ruled that, under section 28 of the National Health Service Act, local health authorities may provide travel warrants for the near relations of patients in a hospital at a considerable distance from home, provided that: (1) the cost cannot be met by the relatives without substantial hardship; and (2) there is urgent reason for the visit because of the patient's serious condition, or the visit would in medical opinion benefit the patient and aid response to treatment. Apart from this arrangement, people visiting long-stay patients in certain institutions, such as sanatoria and mental hospitals, can make the return journey by train on payment of single fare if they obtain in advance an authorised voucher from the hospital.

Pavlov Centenary

A series of lectures to mark the hundredth anniversary of the birth of Ivan Pavlov has been arranged by the Society for Cultural Relations with the U.S.S.R. On Thursday, Oct. 6, Dr. A. S. McPherson is to review Recent Advances in the Study of Conditioned Reflexes; and on Thursday, Oct. 13, Dr. B. H. Kirman will consider the Applications of Conditioned Reflexes to Psychiatry. Both these lectures will be delivered at 14, Kensington Square, London, W.8. On Thursday, Nov. 3, at the University of London Institute of Education, Malet Street, W.C.1, Mr. J. G. Crowther will speak on Pavlov, Scientist and Man: his Place in the History of Civilisation. Each of these three lectures is to be given at 7.30 P.M.

Access to Patients' Records

Patients' hospital records are to be supplied, on request, to the medical boards and medical appeal tribunals of the Ministry of National Insurance, provided that this Ministry first obtains the patient's written consent. Announcing this, the Ministry of Health states that the purpose is to assist in the assessment of claims for disablement benefit under the National Insurance (Industrial Injuries) Act, 1946. Requests will reach hospitals from the regional medical officers of the Ministry of National Insurance. "The cases concerned will ordinarily be those in which the claimant to disablement benefit has received hospital treatment for his industrial injury or disease, although exceptionally case papers relating to treatment not connected with industrial injury may be asked for." The case papers, which will be treated as confidential, will be handled only by the regional medical officers (and their confidential lay staff), boarding doctors, and specialists to whom claimants may be referred, and in the case of appeals the members of the appeal tribunal. The regional medical officer may find it necessary to make extracts of the relevant portions of the case papers which have been taken into account by the medical boards. "The patient will not be put in possession of any information other than the extracts mentioned above which are directly relevant to his claim, and if these extracts contain any information which might be harmful to the claimant the regional medical officer will take care to give it only to the claimant's own doctor or, as appropriate, to his trade union or legal representative."

Kettle Trust Lecture

At the Royal College of Surgeons, Lincoln's Inn F London, W.C.2, on Friday, Oct. 7, at 5 P.M., Dr. Bea Pullinger will lecture on the Significance of Funct Differentiation in Mammary Tumours.

Chartered Society of Physiotherapy

"There is a limit to what a country can afford to even for health." This warning was given by Sir W Jameson, chief medical officer of the Ministry of He the dinner in London last Saturday of the Chartered of Physiotherapy. The health service, he said, could succeed without coöperation by those who worked those who used it; and constructive criticism was we Sir Wilson, who was replying for The Guests to a proposed by Lord Horder, the president, said that therapy had come into its own during the past ten or years; and this progress ran parallel with advances in rehabilitation. Every branch of medicine and now taking advantage of the physiotherapist's skill; among the patients who benefited were the victims of poliomyelitis, and the old and infirm. One a including physiotherapy in the hospital service had be achieve economy, for physiotherapists were too few. C dates were not lacking; but there was a dearth of pre and of teachers, Proposing The Society, Sir Harry P agreed on the need for more able young women to bec teachers. The society was founded 55 years ago, in 18 "an age of great vigour, of liberal outlook, of independe It had always had the support of doctors; and he wish well on behalf of orthopædic surgeons—"there's a vast course of them now, you know." In reply, Dr. W. S Copeman, chairman of the council, pointed out that society now had 17,333 members, compared with 4 in 1 In North America, where physiotherapy was less hig developed, the stock of British physiotherapy st high.

CORRIGENDUM: *Effect of Noradrenaline on the Human Ci lation.*—In this article by Dr. H. J. C. Swan (Sept. 17, p. 5 the caption of fig. 2 should have begun with words: "Blood-pressure and pulse-rate of hypersensit person. . . ."

Appointments

ABRAHAMS, A. M., M.B. Lpool, F.R.C.S.: visiting junior surg Victoria Central Hospital, Wallasey, and St. Catheri Hospital, Birkenhead.

BICKERTON, J. G., M.B. Edin., M.CH. (ORTH.) Lpool, F.R.C.S.E.: ju orthopædic surgeon to hospitals in Chester and Central Wi areas.

CHILDS, J. P., M.A., M.CH. Oxfd, F.R.C.S.: surgeon, South De and East Cornwall Hospital, Plymouth.

COOK, W. H. R., M.B. Lpool, M.R.C.P.: visiting assistant physici Broadgreen Hospital and Southport group of hospitals.

COUPER, E. C. R., M.D. Glasg., F.R.F.P.S. Glasg., D.P.H.: pæ trician, Southport and Ormskirk hospitals.

COX, L. W., M.B. N.Z., F.R.C.S., M.R.C.O.G.: visiting obstetrician gynæcologist, Walton Hospital, Liverpool.

CRAIG, W. J., M.B. Dubl., D.M.R.E.: part-time radiologist, Hert County Hospital.

FENTON, ELIZABETH, M.B. Lpool, D.A.: anæsthetist, Liver regional chest surgical unit.

FREEMAN, D. M. I., M.D. Lpool, M.R.C.P.: visiting assist physician, Warrington group of hospitals.

GASKELL, K. H., M.A., B.CHIR. Camb., M.R.C.S., D.M.R.: whole t class I consultant in diagnostic radiology, Bristol uni hospitals.

HOWELLS, J. G., M.B. Lond., D.P.M.: consultant psychiatr child-guidance services, Ipswich area.

HUTTON, J. N. T., M.B. Durh., D.A.: part-time anæsthetist, East Fever Hospital, Homerton.

KEITH, GLADYS, M.B. Lond., F.R.C.S., M.R.C.O.G.: obstetric surge Mothers' Hospital, Clapton.

KERSLEY, G. D., T.D., M.A., M.D. Camb., F.R.C.P.: director rheumatism unit and adviser, South-Western and Oxf regional boards.

KIRBY, A. C., M.B. Lpool, M.R.C.P., D.C.H.: pædiatrician, Birkenhe hospitals.

MCCANDLESS, ANNE, M.D. Lpool, M.R.C.P.: pædiatrician, Warringt hospitals.

MORTIMER, P. L. F., M.B. Lond., D.A.: anæsthetist, neurosurg department, Frenchay Hospital, Bristol.

ROLLASON, W. N., M.B. Birm., D.A.: consultant anæsthetist, I hospitals.

SHARP, WILLIAM, M.B. Leeds, D.P.M.: consultant physician mental deficiency in western part of East Anglian region.

SHEERS, GEOFFREY, M.A., M.B. Camb.: medical director, ma radiography unit, Plymouth.

SMITH, B. J. D., M.B. Lond.: physician-superintendent, Quant Sanatorium, Somerset.

CANCER OF THE LUNG *

REVIEW OF A THOUSAND CASES

GEORGE A. MASON
F.R.C.S.

n the Regional Chest Centre, Shotley Bridge Hospital, Newcastle-upon-Tyne, and the Department of Thoracic Surgery, Nottingham City Hospital

HE information presented here is based on personal erience gained in the North of England, where since 3 a regional scheme for thoracic surgery has been t up. A smaller amount of material from another tre in the Midlands, with which I have been associated e 1940, has also been drawn on.

ronchial carcinoma is probably now one of the most imonly recognised forms of cancer. Between four five thousand people die from it each year in England Wales. The mortality-rates per million (standardised) ing the first decade of this century were 10·2 for males 7·0 for females, and the corresponding figures for were 100·9 and 23·2. It is impossible to determine ther this increase is real or apparent. During recent s much has been made of the increased proportion hese cases in the necropsy series of large university pitals, but such figures may not necessarily be real es; they may merely mean that interest in cancer he lung having been stimulated by improved facilities diagnosis and treatment, a greater proportion of h patients now die in hospitals with active pathological artments rather than in their own homes or in erculosis sanatoria, where, at any rate in this country, h facilities are usually non-existent or very poor. merly many such patients, especially if they had ting, cough, purulent sputum, and abnormal physical s in the chest, probably languished in sanatoria as s of pulmonary tuberculosis without tubercle bacilli he sputum.

ancer of the lung entails a very large amount of work thoracic surgical clinics. Since the Northern Regional st Surgery Centre was established 15 years ago, we e dealt with more than 1000 cases; in the year up August, 1948, we had about 200 new cases, representing ut a quarter of our non-tuberculosis work. Thus any one time about 30 of the 160 beds in our wards occupied by these patients. Notwithstanding this, cancer registration figures for the area, the population which is almost 3,000,000, suggest that we see only out 60–70% of the actual number of cases.

BLE I—DISTRIBUTION OF BRONCHIOGENIC CARCINOMA BY AGE AND SEX

-group (yr.)	Females	Males	Total
16/30	2 (*2·0%*)	20 (*2·2%*)	22 (*2·2%*)
30/40	18 (*18·4%*)	78 (*8·7%*)	96 (*9·6%*)
40/50	33 (*33·7%*)	276 (*30·6%*)	309 (*30·9%*)
50/60	25 (*25·5%*)	351 (*38·9%*)	376 (*37·6%*)
60/70	19 (*19·4%*)	167 (*18·5%*)	186 (*18·6%*)
70	1 (*1·0%*)	10 (*1·1%*)	11 (*1·1%*)
Total ..	98	902	1000

INCIDENCE BY AGE AND SEX

Though essentially a disease of middle age, cancer the lung may develop in the very old and in children; have seen two or three children, aged about 10 years, ith inoperable growths. Cancer of the lung occurs most mmonly between 45 and 55 years in men and at a ightly younger age in women. Men made up just over 0% of our series (table I), and a similar sex-incidence as characterised most published series.

ÆTIOLOGY

A great variety of occupations is represented in any large series. We have not been able to confirm an early impression that gas and mining workers were among those most often affected, if only because the great bulk of our population consists of workers in the coal and allied industries and because cases are by no means uncommon among agricultural and other rural workers. Perry (1947) of the London Hospital, has found that industrial exposure to arsenic and certain other metallic substances may probably be associated with the ætiology of lung cancer; but such industries are not, so far as I know, represented in our area. Perry has also remarked that arsenic is present in carcinogenetically significant quantities in cigarettes; but this is difficult to reconcile with the disproportionate sex-incidence despite the vast increase of smoking among women, especially since married women appear to be more commonly affected than their single sisters.

There has been no evidence that those exposed to war gases in the 1914–18 war have been unduly liable to cancer of the lung.

The late Prof. Bernard Shaw, of my own university, during the great epidemics after the 1914–18 war, observing considerable displacement of islets of bronchial epithelium in those dying of influenza, suggested that there might be a greater incidence of bronchial carcinoma after fifteen or twenty years.

TABLE II—HISTOLOGICAL TYPES OF BRONCHIOGENIC CARCINOMA

Histological type	Females	Males	Total
Undifferentiated carcinoma	40 (*40·8%*)	321 (*35·6%*)	361 (*36·1%*)
Epidermoid carcinoma	11 (*11·2%*)	341 (*37·8%*)	352 (*35·2%*)
Adenocarcinoma	13 (*13·2%*)	60 (*6·7%*)	73 (*7·3%*)
Unverified ..	34 (*34·7%*)	180 (*19·9%*)	214 (*21·4%*)
Total ..	98	902	1000

ANATOMICAL DISTRIBUTION

The right lung was more commonly affected (52·3%) than the left, but Björk (1947), analysing a smaller number, considered that a similar difference was not statistically significant. The whole left lung is much more often involved than the whole right lung, and an upper more often than a lower lobe. In many cases the lesion is in a small bronchus inaccessible to endoscopy. More rarely the condition formerly known as "diffuse pleural endothelioma" is met; this is characterised by a diffuse thickening of both pleural layers, by effusion, and eventually by matting and invasion of the mediastinum and its viscera. It is now regarded as a low-grade poorly differentiated bronchiogenic carcinoma.

PATHOLOGY

It is generally recognised that there are three histological types of cancer arising from the bronchial epithelium: the undifferentiated or oat-cell type, the epidermoid carcinoma, and the adenocarcinoma, in that order of frequency. The undifferentiated type is much more common in females (table II).

Like Björk (1947) we have found no special relationship either between age and differentiation or between site and histology. The epidermoid growth seems especially liable to be associated with cavitation and gross abscess formation as distinct from a diffuse necrotic process or secondary bronchiectasis, which may occur with any type. Unlike Björk, we find that the prognosis is very much worse in the undifferentiated group.

---

* An address given before the Oslo Kirurgiske Forening on Aug. 23, 1948.

As the initial tumour increases it tends to ulcerate, and the discharge appears as " sputum," or it may bleed, causing hæmoptysis. If the bronchus gets blocked incompletely and infection supervenes, purulent sputum is coughed up ; if the obstruction is complete, the segment of lung collapses, with distortion of the thoracic contents, pain, &c. It is important, from the point of view of differential diagnosis, to realise that, just as in bowel cancers, this obstruction may sometimes be intermittent, presumably as the infective element varies, especially with modern treatment. If septic changes predominate, extensive destruction and abscess formation or even gangrene may develop distal to the obstruction. Extension of this process may cause an effusion or even an empyema. Projections of the growth may obtrude into the opposite bronchus and cause severe dyspnœa. Spread is partly by direct extension into the neighbouring structures but also, in most cases, by the lymphatics and blood-stream.

DIAGNOSIS

Unfortunately cancer of the lung is often clinically silent in its earlier stages. Attention is usually drawn to it, unless it is discovered accidentally by radiography, or by some complication. In our series cough was the commonest first symptom, and after that pain, dyspnœa, lassitude, hæmoptysis, wasting, fever, clubbing, &c. :

Initial symptom	*Cases*		*Initial symptom*	*Cases*	
Cough	266	*(31%)*	Hoarseness ..	8	*(1·0%)*
Pain	205	*(24%)*	Sputum	8	*(1·0%)*
Dyspnœa.. ..	96	*(11%)*	Clubbing	6	*(0·7%)*
Lassitude.. ..	82	*(9·5%)*	Dysphagia ..	5	*(0·6%)*
Hæmoptysis ..	58	*(6·7%)*	Sundry other symptoms	59	*(7·0%)*
Loss of weight ..	27	*(3·1%)*			
Fever	15	*(1·7%)*			
Wheezing ..	15	*(1·7%)*	Total ..	861	
Congestive failure	11	*(1·0%)*			

Hæmoptysis, which occurs at some stage in most cases, is not necessarily an early symptom—it was the first symptom in less than 7% of our cases. Unfortunately both cough and pain are common symptoms which are apt to be treated lightly, even when medical advice is sought. It should therefore be emphasised that a cough occurring in an adult, especially if persistent and incapable of some simple explanation, calls for a most careful investigation by the methods now available. Even so, cases can still be missed, and I can think of at least two in which, after a careful investigation, we did not detect the growths from which the patients ultimately died.

Björk (1947) found, with 112 inoperable cases referred in one year to the Brompton and Cancer Hospitals, that there was an average delay of 8·4 months between the first symptoms and reference to hospital ; and that, whereas the patient was responsible for 3·4 months of this delay, the doctor was to blame for 5 wasted months. Our experience has been similar. Few such patients now linger for long periods in sanatoria ; but regrettably, too many probably still linger in the medical wards of general hospitals until all chance of resection has been lost. The average duration of symptoms in our series was as follows :

Histological type	*1941–43 (215 cases)*	*1944–45 (244 cases)*	*1946–47 (346 cases)*
Undifferentiated carcinoma	7·0 mos. ..	6·9 mos. ..	6·9 mos.
Epidermoid carcinoma ..	10·1 ,, ..	8·5 ,, ..	7·7 ,,
Adenocarcinoma ..	8·2 ,, ..	10 0 ,, ..	6·6 ,,
Unverified	7·0 ,, ..	10·0 ,, ..	6 4 ,,

Though our propaganda has certainly brought us more cases it has not led to any improvement in our material. Though the number of our cases has risen each year from a mere handful fifteen years ago to a steady 175–200 for the last two or three years, the operability-rate has not improved—indeed it has fallen. We now seem to be involved in what at first sight appears to be wasted effort entailed in the investigation of so many hopeless cases..

It was hoped that mass radiography would some improvement, but in our experience this has most disappointing. No appreciable proportion operable patients have come in this way, those patients are excluded who went to such ca because they already had chest symptoms. There is the centre which hangs on to "suspicious" case observation instead of referring them at once for gation. I have known instances where patients been held up for very long periods in this way, having actually become inoperable as a result. T mind much better dividends would have been paid system, whereby every patient entering a hospital whatever purpose, had an X-ray examination of chest.

Differential Diagnosis.—The conditions which bron genic cancer may simulate are legion. I have seen cases in which, after an abdominal operation, a su onset of fever, pain in the chest and shoulder, and a initial hæmoptysis led to bronchial cancer being reg as pulmonary infarction. " Delayed resolution " " unresolved pneumonia " should always be regarde due to carcinoma until proved otherwise. Similarly cases of chronic abscess should be fully investig Pleural effusions and empyemas are usually expressio some underlying pulmonary disease ; in the ca pleural effusions this is often, and in the case of [illegible] occasionally, a carcinoma which may still be Bronchiectasis developing " out of the blue," in later life, and rapidly developing clubbing the fingers (pseudohypertrophic pulmonary arthropathy) should also be suspect.

Radiology.—Dr. Whately Davidson has summa the radiological appearances in our cases as follows. 64% the picture was one of collapse, either of an e lung (24%) or of a lobe (40%). A dense shadow present in the hilus in about 17% ; and in about a cavity with a fluid mimicking a chronic lung ab was seen. A solitary mass was noted in the centre the periphery of the lung in 4%. The remaining c presented as lesions resembling those of apical fi cavernous tuberculosis, and a few as massive effusi We have had only one or two cases of so-called Panc tumour, and one of these was not a lung tumour a but a malignant neurogenic tumour. A few cases, later developed a mass between the scapula and spine, have presented radiologically as absorption the back ends of the third and fourth ribs. The appearances of a tumour must depend on its site, and rate of growth. The direction in which it whether endobronchial or extrabronchial, will dete the shape and size of the opaque area. The developm of complications may *cause a complete* change in whole picture. Early signs are often missed, even radiologists, and the *importance of routine* lateral fi cannot be too strongly urged. Obstructive emphyse may be an early sign, but it seems likely that depende on routine single-plane films without fluoroscopy m be responsible for failure to recognise this change. suspected it may, and should, be confirmed by tak radiograms both in different planes and in differ phases of respiration. A common first appearance is increase in the size and density of a root shadow. E this may pass unobserved. When suspicion is rais careful tomography may disclose a mass protrud into the bronchial lumen or causing moderate compr sion. In only a small proportion of the " collaps cases will efficient tomography not show either a defin mass or at least a very suspect area of greater dens at the apex of the pyramid of collapsed lung tiss Tomography is especially valuable where the growth in a bronchus inaccessible to bronchoscopy, and *distinguishing between an abscess and* the cavity of lasm which is breaking down. The characteristic arances of the latter are indeed best seen in tomo-s: the outer contour may be smooth, round, or and with slight lobulation, unless the growth has dy become more generally invasive: its wall, ng a rind-like appearance, is usually very thick; its internal contour presents nodules of smooth or ular outline, which protrude into the lumen. There ll some scope for the use of iodised oil. Bronchial sion thus demonstrated may be shown by an abrupt verse shadow or as a finely tapering off "rat's tail."

onchoscopy—and of course the taking of a biopsy imen, if possible—is an essential routine investigation. ugh many growths are in bronchi inaccessible to such ection, mediastinal glandular involvement may often ecognised and assessed by the appearances of the carina. It is important to remember that a broncho-y which is negative at the outset of a long period of rvation may give positive findings when repeated .

ploration.—Often an exploration is made to confirm diagnosis; this usually means a pneumonectomy—ss the condition is found to be too far advanced—use if there is an X-ray shadow there is usually a able lump, and generally speaking the only safe g to do with a palpable lump is to remove it. On e half-dozen occasions this policy has led to our oving lungs for non-malignant conditions, including d pneumonia, calcified hæmatoma, tuberculoma, thoma, and a chronic abscess containing a tooth.

TREATMENT

e recommend exploratory thoracotomy in all cases out obvious contra-indications such as clinical or ological evidence of dissemination, bad general ition of the patient, extension of the growth too e to the carina or into the mediastinal viscera, and s widening or distortion of the carina. We have now nt that advanced age, poor cardiorespiratory reserve, hysema, and arteriosclerosis, especially coronary fficiency, are also contra-indications.

hough we have never yet found an operable lesion he presence of recurrent palsy, diaphragmatic palsy s not necessarily indicate malignant invasion of the enic nerve, which may merely be involved in an ciated inflammation. Empyema is certainly not a tra-indication. Our policy of investigating every case empyema completely, including bronchoscopy and nchography, before completion of convalescence has ught us not only a harvest of previously unrecognised nchiectatics but also an occasional operable growth. ilarly, the fact that an effusion is bloodstained does essentially imply that the underlying growth is perable. I can recall such a patient who survived umonectomy and worked as an outside manager of a yard, dying from some obscure wasting condition, sibly metastases, three years later. Cases in which parietal pleura has been invaded also may do e well, provided the overlying chest wall or dia-agm, as the case may be, is removed with the growth; the other hand, removal of a growth with the overlying , when they are invaded, is nearly always followed by urrence within a few months. It may be necessary remove the pericardium to complete a satisfactory noval and even to encroach on to the heart; indeed, a dier in whom it was necessary to make a major roachment into the auricle to obtain good clearance d, after two years' heavy manual work, from a leaking eurysm of the auricle. We habitually make a barium amination of the œsophagus in doubtful cases before eration, because we have never found the case operable ere the œsophagus has been found to be distorted.

OPERATIVE MANAGEMENT

Preoperative preparation includes thorough training in respiratory exercise and postural drainage. The patient is made familiar with the wearing of a B.L.B.-type oxygen mask. Oral sepsis is corrected as far as possible. Anæmia is treated with iron and, if need be, by transfusion. Intrabronchial and systemic administration of penicillin, &c., is necessary in "wet" cases.

As in all chest surgical cases, the anæsthetist participates fully in the preoperative investigations and consultations, to ensure intelligent management of the case during operation, and as fully in the subsequent care of the patient. The anæsthetist is also responsible for the maintenance of a clear airway, efficient respiration, and adequate oxygenation; this entails, inter alia, control of tracheobronchial secretions. It is the anæsthetist's responsibility to combat shock and to supervise operative and postoperative resuscitation and the replacement of blood, &c., by transfusion.

The bronchus of the lung to be removed is occluded with a Thompson cuff introduced under local anæsthesia, as is the Magill intratracheal tube for the subsequent administration of the anæsthetic. The anæsthetic agents used are thiopentone and cyclopropane; but, if diathermy is used throughout the operation, thiopentone, curare, and nitrous oxide and oxygen are given. The further administration of thiopentone and curare, a method increasingly relied on, is with a small Gordh-type needle usually fixed into one of the small veins on the back of the hand. Controlled respiration of the type introduced by Geudel in America and by Nosworthy in England is now always used by our anæsthetist, Dr. Joan Millar. The spiropulsator of Crafoord is not usually available in this country, but I am impressed by its value, especially in long operations.

Some surgeons prefer to operate on such patients in the face-down position, but we always use the standard lateral thoracotomy position, and control bronchial secretions by intratracheal suction and, when possible, by means of the Thompson cuff tampon. We are convinced that the use of this cuff alone has enabled us to operate on many patients who would otherwise have been too "wet" to deal with.

Access to the chest is usually through the bed of the fifth or sixth rib. If the lung is densely adherent to the parietes, it is preferable to mobilise it by an extensive extrapleural strip: this is often accompanied by severe bleeding, but we proceed with this as rapidly as possible, controlling the bleeding with hot packs and transfusion, to avoid delay in reaching the hilus. Here our practice differs from that in Scandinavia, and perhaps we are

TABLE III—RESULTS OF PNEUMONECTOMY IN BRONCHIOGENIC CARCINOMA

* Two lobectomies, in addition, were done in 1944: one patient died after operation, and the other died two years later with secondaries.

As the initial tumour increases it tends to ulcerate, and the discharge appears as "sputum," or it may bleed, causing hæmoptysis. If the bronchus gets blocked incompletely and infection supervenes, purulent sputum is coughed up; if the obstruction is complete, the segment of lung collapses, with distortion of the thoracic contents, pain, &c. It is important, from the point of view of differential diagnosis, to realise that, just as in bowel cancers, this obstruction may sometimes be intermittent, presumably as the infective element varies, especially with modern treatment. If septic changes predominate, extensive destruction and abscess formation or even gangrene may develop distal to the obstruction. Extension of this process may cause an effusion or even an empyema. Projections of the growth may obtrude into the opposite bronchus and cause severe dyspnœa. Spread is partly by direct extension into the neighbouring structures but also, in most cases, by the lymphatics and blood-stream.

DIAGNOSIS

Unfortunately cancer of the lung is often clinically silent in its earlier stages. Attention is usually drawn to it, unless it is discovered accidentally by radiography, or by some complication. In our series cough was the commonest first symptom, and after that pain, dyspnœa, lassitude, hæmoptysis, wasting, fever, clubbing, &c.:

Initial symptom	*Cases*		*Initial symptom*	*Cases*	
Cough	266	(*31%*)	Hoarseness ..	8	(*1·0%*)
Pain	205	(*24%*)	Sputum	8	(*1·0%*)
Dyspnœa.. ..	96	(*11%*)	Clubbing	6	(*0·7%*)
Lassitude.. ..	82	(*9·5%*)	Dysphagia ..	5	(*0·6%*)
Hæmoptysis ..	58	(*6·7%*)	Sundry other symptoms	59	(*7·0%*)
Loss of weight ..	27	(*3·1%*)			
Fever	15	(*1·7%*)			
Wheezing ..	15	(*1·7%*)	Total ..	861	
Congestive failure	11	(*1·0%*)			

Hæmoptysis, which occurs at some stage in most cases, is not necessarily an early symptom—it was the first symptom in less than 7% of our cases. Unfortunately both cough and pain are common symptoms which are apt to be treated lightly, even when medical advice is sought. It should therefore be emphasised that a cough occurring in an adult, especially if persistent and incapable of some simple explanation, calls for a most careful investigation by the methods now available. Even so, cases can still be missed, and I can think of at least two in which, after a careful investigation, we did not detect the growths from which the patients ultimately died.

Undifferentiated carcinoma	7·0 mos. ..	6·9 mos. ..	6·9 mos.
Epidermoid carcinoma ..	10·1 ,, ..	8·5 ,, ..	7·7 ,,
Adenocarcinoma ..	8·2 ,, ..	10 0 ,, ..	6 6 ,,
Unverified	7·0 ,, ..	10·0 ,, ..	6 1 ,,

Though our propaganda has certainly brought us more cases it has not led to any improvement in our material. Though the number of our cases has risen each year from a mere handful fifteen years ago to a steady 175–200 for the last two or three years, the operability-rate has not improved—indeed it has fallen. We now seem to be involved in what at first sight appears to be wasted effort entailed in the investigation of so many hopeless cases.

It was hoped that mass radiography would some improvement, but in our experience this has most disappointing. No appreciable proportion operable patients have come in this way, those patients are excluded who went to such cen because they already had chest symptoms. There the centre which hangs on to "suspicious" observation instead of referring them at once for gation. I have known instances where patients been held up for very long periods in this way, having actually become inoperable as a result. mind much better dividends would have been paid system, whereby every patient entering a hosp whatever purpose, had an X-ray examination chest.

Differential Diagnosis.—The conditions which genic cancer may simulate are legion. I have seen cases in which, after an abdominal operation, a onset of fever, pain in the chest and shoulder, and a initial hæmoptysis led to bronchial cancer being as pulmonary infarction. "Delayed resolution" "unresolved pneumonia" should always be regarde due to carcinoma until proved otherwise. cases of chronic abscess should be fully Pleural effusions and empyemas are usually some underlying pulmonary disease; in the pleural effusions this is often, and in the case of empy occasionally, a carcinoma which may still be oper Bronchiectasis developing "out of the blue," espec in later life, and rapidly developing clubbing the fingers (pseudohypertrophic pulmonary arthropathy) should also be suspect.

Radiology.—Dr. Whately Davidson has summari the radiological appearances in our cases as follows. 64% the picture was one of collapse, either of an ent lung (24%) or of a lobe (40%). A dense shadow present in the hilus in about 17%; and in about 1 a cavity with a fluid mimicking a chronic lung abs was seen. A solitary mass was noted in the centre or the periphery of the lung in 4%. The remaining ca presented as lesions resembling those of apical fib cavernous tuberculosis, and a few as massive effusio We have had only one or two cases of so-called Panco tumour, and one of these was not a lung tumour at but a malignant neurogenic tumour. A few cases, wh later developed a mass between the scapula and spine, have presented radiologically as absorptions the back ends of the third and fourth ribs. The X appearances of a tumour must depend on its site, durat and rate of growth. The direction in which it exte whether endobronchial or extrabronchial, will determ the shape and size of the opaque area. The developme of complications may cause a complete change in t whole picture. Early signs are often missed, even radiologists, and the importance of routine lateral fil cannot be too strongly urged. Obstructive emphysema may be an early sign, but it seems likely that dependen on routine single-plane films without fluoroscopy m be responsible for failure to recognise this change. suspected it may, and should, be confirmed by taki radiograms both in different planes and in differe phases of respiration. A common first appearance is increase in the size and density of a root shadow. Ev this may pass unobserved. When suspicion is rai careful tomography may disclose a mass protrud into the bronchial lumen or causing moderate compr sion. In only a small proportion of the "collapse cases will efficient tomography not show either a defini mass or at least a very suspect area of greater densit at the apex of the pyramid of collapsed lung tiss Tomography is especially valuable where the growth in a bronchus inaccessible to bronchoscopy, and i distinguishing between an abscess and the cavity of ding 4 out of 33 (12·12%) alive for 4·5–7 years, and t of 57 (15·8%) alive for 3–4 years.

PALLIATIVE TREATMENT

orphine and cocaine given in increasing doses with hol will often afford reasonable relief and make tence tolerable. More severe neuralgic pains may d to intervertebral injections of anæsthetics or may a require cordotomy, and I have also seen cases re division of the phrenic nerve has helped to relieve iously intractable painful dragging sensations. netimes the intense pain of bony secondary deposits require osteotomy and the curetting out of the plastic tissue.

ormerly the suffocative symptoms of mediastinal npression could be helped only by division of the er sternum; this may still at times be useful, but such nptoms can usually be relieved by X-ray therapy. such cases X-ray therapy should never be withheld, ause it sometimes affords dramatic relief, and also ause the growth may prove to be a radiosensitive nphocytoma rather than a carcinoma.

neumonectomy itself should not be overlooked as a liative operation, especially in cases of pseudohyperphic pulmonary osteo-arthropathy and where pulnary infection is causing distress. Once the problem istula and empyema after pneumonectomy is mastered, scope of the operation in this field may well be lened.

ariations in the natural course of cancer of the lung ke it difficult to assess the results of treatment. I ve known a case with a continuous history extending er about five years, but we know that most cases run very much shorter course, whatever the treatment. I n recall two patients in whom, though the growth s probably still removable, gross metastases scattered roughout the pleura were considered to preclude rther treatment; subsequently these patients did avy manual work for over a year before their strength clined and they ultimately died.

Until we can get these cases at a much earlier stage, ey will continue to be a disheartening part of our work. ven so, despite all the risks and the work involved, eumonectomy offers the best hope of long survival d should be considered whenever possible.

I am greatly indebted to my colleagues, Mr. S. G. Griffin d Mr. W. C. Barnsley, assistant surgeons in the Regional est Surgery Centre, and to Mr. W. Buckley, assistant oracic surgeon to Nottingham City Hospital, for all the ouble they have taken to obtain this information for me, ides the active part they have played in the management the cases. Mr. Barnsley has done a vast amount of work this connexion, and it is largely on this that I have drawn.

TREATMENT OF STATUS EPILEPTICUS

C. W. M. WHITTY
B.M., B.Sc. Oxfd, M.R.C.P.

MARGARET TAYLOR
B.M. Oxfd

From the Department of Neurology, Radcliffe Infirmary, Oxford

STATUS epilepticus, the occurrence of several grand-mal convulsions without recovery of consciousness between each, should be looked on as a grave emergency. If effective measures are not taken promptly to arrest the fits, the patient is likely to die.

The use of modern chemotherapy in the late war allowed the survival of many patients with severe brain wounds which would formerly have proved fatal. Hence there are more traumatic epileptics, and ipso facto cases of status epilepticus, in the community. The subject is inadequately dealt with in standard textbooks; and the occurrence of several probably avoidable deaths from this cause has prompted us to make this brief review of 25 cases, mostly of the symptomatic group, and to mention one régime which in our experience has proved a safe and usually effective remedy.

Status epilepticus can nearly always be cured if correct treatment is instituted early. Such treatment must not be allowed to obscure the medical or surgical measures required to deal with the underlying lesion in symptomatic epilepsy. However, even in these cases, arresting the fits is generally a life-saving measure and certainly an essential preliminary to further diagnosis and treatment, which may have to be delayed until special facilities are available.

MATERIAL

Our material was gathered from either the Radcliffe Infirmary or the head-injury bureau at Wheatley Military Hospital, and the records of 36 patients were examined, of whom 12 had died. Information was inadequate for detailed study in 11 cases; of the remaining 25 patients (tables I and II), 17 were seen personally by one or other of us, details of the remaining 8 being obtained from case-records. In 2 patients two separate attacks of status epilepticus occurred; 3 patients appeared to be idiopathic epileptics; and 22 had some organic brain lesion as the presumed cause of the convulsions. Necropsy was performed in all the fatal cases; in none of them was any definite cause found for their death apart from the fits. In those with brain wounds there had been early and adequate neurosurgical treatment, and cases with an infective process showed evidence that this had been controlled by medical treatment.

FINDINGS

If one compares the non-fatal cases (table I) with the fatal (table II), two points clearly emerge. In the fatal cases the interval between the onset of status epilepticus and the beginning of treatment was usually much longer than in the non-fatal cases, and the duration of status epilepticus was longer in the fatal cases than in the others. (The duration was taken to be the period in which convulsive movements continued without any recovery of responsiveness to questions or commands. In many cases it was subsequently found that a far longer period was occupied by a total amnesia. This was probably due partly to the drugs used in treatment, though in some cases it may have represented an extension of the epileptic process.)

The type of treatment, on the other hand, seems to vary widely in both groups, and at first sight it might seem that the particular treatment used was of little importance. The detailed course of individual cases, however, suggests that this is a false impression. There is evidence that paraldehyde is the drug of choice, both wrong, but we do not like to spend more than two, or at most three, hours on such an operation.

The present practice is to cut the bronchus across as close to the carina as possible and to close it with a series of fine interrupted linen-thread sutures. Alternate sutures of this series are used to anchor a flap of parietal pleura over the bronchial stump. Penicillin-sulphathiazole powder is placed in the mediastinal bed round the stump, and the same drugs are given systemically for 10–14 days afterwards. Whenever the pleural effusion is aspirated subsequently, penicillin 100,000 units in 5 ml. of fluid is left in the pleural cavity.

COMPLICATIONS AND MORTALITY

The mortality from these operations has been heavy (table III), but it must be remembered that, of necessity, many cases which are now regarded as unsuitable have been undertaken in the past; the material occurs in the age-groups liable to cardiovascular and other degenerative disasters; and, unfortunately, some deaths from unexpected mishaps have taken place in what might have been our best material, but I think that many valuable lessons have been learnt from our bitter experience. Our mortality is also weighted by borderline cases, the inoperability of which could not be certainly recognised until some irretrievable step had been taken. This will always remain so, to some extent, unless such patients are not given the only likely chance of recovery.

TABLE IV—INCIDENCE OF FISTULA AND EMPYEMA AS COMPLICATIONS OF PNEUMONECTOMY FOR CARCINOMA

Year	Cases	Fistulæ requiring drainage	Empyemas requiring drainage	Deaths from fistula and empyema	Deaths from other causes
1943	13	4	2	2	2
1944	28	12	..	5	4

1947	42	8	1	3	6
Part of 1948	19	..	1	1	2
Total ..	184	37	6	14	25

Bronchial fistula and empyema are the most serious complications of pneumonectomy (table IV). The frequency of empyema, in the absence of fistula, has diminished with modern methods, but we still have occasional tragic difficulties with unexpected and most refractory empyemas, usually due to penicillin-resistant organisms. It is not perhaps generally realised that an appreciable number of the late deaths after pneumonectomy, say as long as two years afterwards, may be due to delayed opening of a bronchial fistula. We always seem to be about to settle the fistula problem, and certainly technical improvements have been made and the position is very much better, but I doubt if the matter has been completely solved.

We have explored 353 out of the 1000 patients, and in these pneumonectomy was possible in 202. Of the patients who underwent pneumonectomy, 54 died a month, as did 32 of the 151 who were merely . Of those who underwent pneumonectomy and the first month, 68 died from metastases, &c., another 18 from other causes.

RÖNTGEN THERAPY

Through the coöperation of Mr. C. J. L. X-ray treatment is given to the patients who operation or are unsuited for it, to those whose is found to be inoperable on exploration, to all undifferentiated growth whether operated on or not to cases in which growth is present in the glands at operation.

The radical course extends over five or six 4500 r being given for undifferentiated growths 5500 r for epidermoid growths. Four or five field used—lateral, anterior, and posterior. The contou the chest are assessed by a physicist to ascertain correct beam directions. Pyridoxine is found helpf controlling nausea and sickness. *Oral sepsis and an* are corrected as in the preparation for *pneumonect* and the erythrocyte level is maintained as fa possible during the course, being checked by repe blood-counts.

When little more than palliation is looked for, a co of 2500–3000 r is given in three weeks. In case mediastinal obstruction 500 r is given in one and supplemented as the patient's progress seem indicate.

Great symptomatic and radiological improvement follows a course of X-ray therapy, but unfortunatel the great majority of cases this is not maintained and patient dies within a few months (table V). We 42 patients alive out of 445 so treated for periods ran from 5 months to 5·5 years. This includes 2 out of (1·77%) alive for 5 years, and 6 out of 125 (4·8%) for 2–3 years. These figures must be compared with pneumonectomy figures (table VI); 62 out of 202 pati alive from 2 months to 7 years after pneumonecto

checked the more probable is a fatal outcome. This emphasised by the following figures:

Duration of status epilepticus	*No. of deaths*	*No. of recoveries*
Under 3 hr.	0	6
3–12 hr.	4	8
12–24 hr.	1	2
Over 24 hr.	6	0
Total	11	16

In many cases where fits have been finally controlled ter some hours irreversible changes seem to have ken place and death ensues after a further period of ma. This was so in 5 of the 11 cases given in table II.

our experience paraldehyde is a safe and effective ug in this condition. The principle of treatment is to tablish as rapidly as possible an effective anticonvulnt blood-paraldehyde level and to maintain this until e fits stop.

The régime we consider advisable for an average adult as follows:

(1) As soon as possible 8–10 ml. of paraldehyde is injected to the gluteal muscle, and the site of injection is massaged. e paraldehyde need not be sterilised. This treatment ually stops the fits within half an hour.

(2) If the fits continue, 5 ml. of paraldehyde intramuscularly given every half-hour until they cease. The persistence of cal twitching without any tendency to spread does not quire further sedation, and attempts to eliminate these tirely may lead to a dangerous level of narcosis.

(3) If the patient's general condition indicates it, an travenous glucose-saline or plasma drip is given at the rate one bottle in three hours. This will also provide a conient method of continuing the administration of paralehyde, either by intermittent injections into the drip tubing, in solution in the drip fluid in any required concentration, nce it is soluble 1 in 8 in physiological saline solution.

In practice most cases will be controlled by the intrauscular injections and a drip will not be required. owever, if fits recur as the effect of the paraldehyde ears off, an intravenous drip gives a means of adjusting curately blood-paraldehyde level so that fits are ontrolled but coma is not too deep. This is important, nce drugs which control status, to be effective, must be used in doses which abolish consciousness. Moreover, if fits continue for long, intravenous fluids may be necessary to combat either obvious dehydration or the accumulation of metabolites in tissue fluids and blood. An intramuscular injection in patients whose circulatory state suggests that it will not be absorbed is clearly valueless, and in these cases a drip should be set up at once.

For children the dosage in the régime described above is smaller; but it is still higher than is generally realised, and even in infants aged only a few months 2 or 3 ml. of paraldehyde intramuscularly must be given to be effective.

The value in certain cases of an adequately maintained blood-paraldehyde level, which can best be achieved by continuous intravenous drip, is well illustrated in the following case, which in our experience was unusually severe:

Case 26.—A man, aged 27 (not included in table I) was admitted to hospital in status epilepticus with fits every

TABLE III—CASE OF STATUS EPILEPTICUS TREATED WITH INTRAVENOUS PARALDEHYDE SOLUTION

Hours since admission to hospital	Paraldehyde dosage	Method of dosage	Fit frequency (no. per hr.)
1–2	None	..	12
3–7	2 ml. hourly	Intermittently into drip tubing	12
8–11	4 $^{1}/_{2}$ ml. hourly		6
12–20	2 ml. hourly		4
21–24	2 $^{1}/_{2}$ ml. hourly		4
25–28	6 ml. hourly	In solution in drip fluid 18 ml. per bottle of 540 ml.	4
29–31	6 ml. hourly		1
32–35	6 ml. hourly		None
36–43	None		1 in last hour
44–48	6 ml. hourly		None (began to respond to stimuli)
49–54	3 ml. hourly		None (able to swallow)
55–64	None		8 in last 2 hr.
65–67	3 ml. direct I.V. 3 ml. hourly		None (able to talk)

In the next 24 hr. the drip was stopped and paraldehyde 2 drachms 4-hourly by mouth was given. This was changed gradually to phenobarbitone gr. 1 q.d.s.

from the rapidity of its effect in checking convulsions and from its success in abolishing fits in some cases where barbiturates had failed. These points are illustrated in the following brief case-records.

Case 2.—A boy, aged 18, had a gunshot wound of the right frontal pole of the brain. After neurosurgical débridement *this healed without incident. The patient returned to civilian* life and to light employment.

Some three years after his injury he suddenly had a series of grand-mal convulsions without recovery of consciousness between each. *Within three-quarters of an hour of their* onset he was taken to a local hospital, where he was given 5 ml. of paraldehyde intramuscularly. Within half an hour full convulsions ceased, and within three hours of the onset the patient could be roused to answer questions correctly, though he was still very drowsy.

He was transferred two days later to another hospital, where he again went into status epilepticus. On this occasion he was given gr. 5 of sodium phenobarbitone intramuscularly within twenty minutes of the onset. However, his fits continued for a further hour, when they tailed off gradually. He was then given gr. 1 of phenobarbitone by mouth t.d.s. and has reported no further fits.

Case 15.—A girl, aged 11 months, had been off her feeds and had had diarrhœa for some weeks. She seemed to have recovered from this and was feeding well again, when she suddenly developed status epilepticus. On admission to hospital two hours later she was immediately given 5 ml. of paraldehyde intramuscularly and gr. 2 of phenobarbitone by mouth. Within a quarter of an hour the convulsions ceased. However, occasional twitchings, mainly of the mouth and face, started again some twelve hours later. These never proceeded to grand-mal convulsions and they cleared entirely in about two days. After the initial paraldehyde the patient was given gr. $^1/_4$ of phenobarbitone four-hourly during her stay in hospital. Some months later she had a further status epilepticus, in which she died.

The dose of 5 ml. of paraldehyde in this case probably unnecessarily high and is not recommend as a routine. However, an initial dose of 2 or 3 in infants over the age of 6 months, and 1 or 2 ml. younger infants, is usually necessary to end the fits.

In the foregoing cases intramuscular *ended the convulsions within an hour or so.* Wh barbiturates were used the effect was more delay Thus in case 3 (table I) after the administration of gr of sodium phenobarbitone intravenously the fits c tinued for some four hours, and in case 7 (table despite gr. 6 of sodium phenobarbitone intramuscular the fits continued for three hours, and in each c barbiturates had to be repeated.

In the following case paraldehyde appeared to ha a rapid effect when barbiturates had not modified status epilepticus:

Case 13.—A woman, aged 54, developed status epilepti some ten days after surgical removal of portions of b frontal lobes. She was in hospital at the time, and wit half an hour of the start she was given gr. 3 of sodium phe *barbitone intramuscularly. This was repeated in half* hour, because the fits continued. However, three-quart of an hour later she was still having grand-mal convulsio at intervals of about five minutes. Then, at about 6 P. she was given 10 ml. of paraldehyde intramuscularly. With half an hour the fits ceased entirely and did not recur. T patient slept through that night and thereafter remain drowsy and confused, though able to respond to questio for a further twelve hours. On phenobarbitone and hydant given regularly she has had no further fits.

DISCUSSIONS AND CONCLUSIONS

Prompt measures must be taken to end the convulsio in status epilepticus. The longer the fits contin

iliac fossa. A large gangrenous appendix epiploica was d on the outer side of the cæcum. It was excised and the men closed without drainage. Recovery was uneventful.

ise 4.—A married man, aged 42, was admitted in 1931 plaining of acute abdominal pain of some 24 hours' tion. T., 99·6; P., 100; R., 26. Tenderness was found ie lower quadrants of the abdomen. Per rectum there was erness high up in the rectum. Laparotomy revealed a large grenous appendix epiploica attached to the lateral wall of upper sigmoid colon. It was removed and recovery was ventful.

ase 5.—A married women, aged 46, was admitted in 1935 plaining of acute abdominal pain which had begun denly 12 hours previously. T., 99·2; P., 84; R., 26. re was tenderness all over the lower abdominal quadrants, (per vaginam) in the posterior fornix. Laparotomy aled a large gangrenous epiploica on the anterior surface he lower part of the sigmoid colon. The gangrenous mass excised. Recovery was uneventful and the patient was harged on the 9th postoperative day.

ase 6.—A married man, aged 41, was admitted in 1938, plaining of acute abdominal pain of 20 hours' duration. 100; P., 98; R., 30. Some tenderness was found in the iliac fossa, and (per rectum) high up in the rectal wall. ite-cell count, 16,200. Laparotomy revealed a gangrenous endix epiploica attached to the outer wall of the lower moid colon. The gangrenous appendage was excised and patient made an uneventful recovery.

ase 7.—A married man, aged 36, was admitted in 1939. estinal obstruction had been diagnosed. T., 99; P., 92; 26. Examination showed some abdominal distension, l tenderness in the left iliac fossa; per rectum nothing normal was discovered. Laparotomy revealed a grossly lamed appendix epiploica on the inner side of the upper t of the sigmoid colon. To this appendix was attached a roll great omentum. The omentum was freed and the appendix ploica excised. Recovery was uneventful.

Case 8.—A stoker, was admitted to a Naval hospital in 41, complaining of acute abdominal pain of 12 hours' ration. T., 100; P., 98; R., 30. There was tenderness the left iliac fossa and guarding of the abdominal wall er that region. White-cell count, 12,500. Per rectum thing abnormal was discovered. On abdominal section a ge gangrenous appendix epiploica was exposed on the wall the upper part of the sigmoid colon; it was excised. covery was uneventful.

ANATOMY

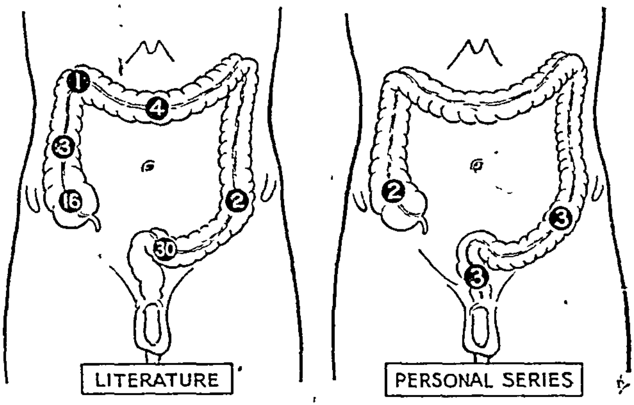
The appendices epiploicæ are found along the whole gth of the large bowel, with the exception of the rectum; ey are most numerous in the transverse and sigmoid lons (see figures). Each appendage is composed of a sac peritoneum containing only fat, with a single artery d a single vein entering and leaving at the attachment the bowel wall. This attachment is a pedicle which ay be of varying size and shape, elongated and narrow, ort and wide. The size of the appendices epiploicæ variable, and they tend to be larger in obese persons. ere is no evidence of any lymphatic drainage.

The fatty tissue of the appendices epiploicæ is conuous with that in the subserous layer of the bowel all. As a rule there is no continuity with any other yer. But McGrath (quoted by Hunt 1919) pointed it that the appendages arose from the bowel over or ar the entry of vessels through the muscle layer. It at these points of entry of vessels that diverticula e sometimes found, and thus appendices epiploicæ re sometimes related to, or even contain, small iverticula.

On occasion, the sac of an umbilical, inguinal, or moral hernia may be found to contain an appendix piploica.

FUNCTION

It seems possible that the appendices epiploicæ form storehouse for fat (Griffin et al. 1942). Patterson quoted by Fiske 1936) has ascribed to them a "buffer" action during the movements of peristalsis. Robinson (quoted by Klingenstein 1924, and by others) suggested that they play a part in the absorptive function of the large gut. It appears more certain that they have a protective and localising action similar to that of the greater omentum in the presence of infection. Klingenstein (1924) found appendices epiploicæ wrapped round an acutely inflamed appendix vermiformis; Hunt (1919) described them forming a protective mass round an inflamed diverticulum. A further function has been suggested by Pines et al. (1941); they described them as protective fat pockets which can take up redundant intestinal vessels when the bowel is collapsed, and which can protect these vessels from obliteration by pressure when the bowel is distended.



The position of diseased appendices epiploicæ as found in a study of the literature and in our personal series.

SURGICAL SIGNIFICANCE

Whatever may be the function of the appendices epiploicæ, they have definite surgical significance. Owing to their shape they are liable to torsion of their pedicle, the more so the larger the size of the appendage relative to the size of the pedicle. Movements of the viscera obviously play a part in the initiation of torsion, but other factors have not been determined. Klingenstein (1924) described one case associated with acute hæmorrhagic pancreatitis and one with acute gangrenous appendicitis. He suggested that sudden migration of the appendage to the seat of infection might initiate torsion.

Torsion of the pedicle cannot always be demonstrated. It is possible that in some of these cases infarction of an appendix epiploica may be caused by embolism or thrombosis of its vessels.

The sequelæ of torsion or infarction depend to some extent on the degree and rapidity of interference with blood-supply. Chronic torsion may give rise to fat necrosis, saponification of the fat, fibrosis, perhaps even calcification. The pedicle may separate from the bowel wall and the separated appendage then forms a foreign body within the peritoneal cavity (Hunt 1919). In more acute cases, hæmorrhages occur into the fatty tissue. Such appendages may organise, and may acquire adhesions to other viscera or to the abdominal wall if the process is limited and remains uninfected. Or a hæmorrhagic gangrenous mass may develop, and this may become infected by direct microbic invasion from the lumen of the bowel because of interrupted continuity (Hunt 1919). In those appendages related to a diverticulum infection may be acquired from the diverticulum. Late stages of the process lead to the formation of an abscess, localised or diffuse peritonitis (Moore 1940).

The inflamed appendage of an acute torsion may acquire adhesion to other viscera or the parietes. As in chronic torsion, a band is thereby formed, and round this sooner or later a loop of bowel may become twisted and obstructed.

five minutes. He had had serial epilepsy for four days previously, and had had an unknown amount of sodium cyclonal intravenously followed by paraldehyde intramuscularly, with only a slight reduction in the number of his fits. Since he appeared dehydrated, a glucose-saline drip was set up at a rate of about 540 ml. (1 bottle) in three hours, through which paraldehyde was given. The subsequent course of fits and medication are shown in table III. *It will be seen that intermittent dosage had little effect, but the maintenance of an effective blood-paraldehyde level stopped the fits within six hours. The very large doses which may be safely used when occasion demands is also well shown. This patient had 202 ml. of paraldehyde intramuscularly in three days.*

Additional clinical evidence of the value of paraldehyde is provided by the experimental work of de Elío et al.[1] who find that intravenous paraldehyde promptly abolishes both the convulsions and the abnormal cortical electrical activity of experimentally induced epilepsy in animals, and the fits induced sometimes during cerebral operations in man. The rapidity with which paraldehyde acts is strikingly shown in their work, and they remark that once the epilepsy has ceased it usually does not recur even though the pharmacological effect of the paraldehyde has worn off.

Other remedies are undoubtedly effective in status epilepticus, but the rapid action and relative safety of paraldehyde make it the drug of election. If it is not available, an attempt should be made immediately to stop the fits by other means, because it is essential that the fits be interrupted as rapidly as possible. If phenobarbitone is used it should be given in doses of gr. 6–12, smaller doses being of little value, and preferably in the "soluble" form by intramuscular or intravenous route. Thiopentone in anæsthetic doses may be used, or chloroform anæsthesia if no other remedy is at hand. But the effect of these methods is often short-lived, and it may be necessary to establish heavy sedation by other means and to maintain this for twenty-four hours or longer afterwards if the fits tend to recur. The respite given by the immediate measures is probably best used in establishing paraldehyde sedation. Though cases of status epilepticus at times seem to subside practically without treatment, it is safest to regard every case as potentially fatal and to act accordingly.

Once status epilepticus has been controlled, the patient must be put on regular anticonvulsant therapy, of which the barbiturates and hydantoins remain the most convenient and widely used. The patient should clearly understand that the regular use of these medicines for an indefinite period is essential to avoid a recurrence of the convulsions.

The commonest setting for status epilepticus is as an episode or the terminal event in idiopathic grand-mal epilepsy. However, it can also occur as the first manifestation of a traumatic epilepsy or of a symptomatic epilepsy from cerebral neoplasm, as Clark and Prout[2] have noted. When status epilepticus occurs during the course of an established epilepsy it is often preceded by an increased frequency of individual attacks, which may become so numerous as to constitute serial epilepsy. This gives timely warning of a possible status epilepticus; hence anticonvulsant therapy can be appropriately increased. In 9 of the 25 cases reviewed here there was such a preliminary increase of fits. The omission of the patient's usual anticonvulsants in either symptomatic or idiopathic epilepsy is a common precipitating factor of status epilepticus. This should be explained to those liable to be careless about their medication.

SUMMARY

The treatment and course of 25 cases of status epilepticus are reviewed.

This condition constitutes a grave medical
and may be fatal unless the fits are rapidly

A régime of treatment considered to be safe effective, based on the use of intramuscular or i venous paraldehyde, is described.

Our thanks are due to Dr. Victoria Smallpeice, phy in charge of the children's department, Radcliffe Infirm under whose care four of the patients were admitted, and Dr. W. Ritchie Russell, who provided facilities for revie the head-injury cases and helped us with valuable criti

FIRST SURGICAL ASSISTANT, KING'S COLLEGE HOSPITAL

Morbid conditions of the appendices epiploicæ, whi cause symptoms and signs of acute or subacute abdomi disease, and necessitate urgent surgery, are uncommo 64 such cases have been reported (Hunt 1919, Kling stein 1924, Fiske 1936, Pines et al. 1941, Marinis a Check 1949). *This number does not include those runni* a chronic course, those in which appendices epiploi situate within hernial sacs are diseased, those associat with other acute disease, or those in which diseas appendices epiploicæ are found incidentally at operatio or at autopsy. To these previous reports and review we wish to add 8 further cases from the case-records *of one of us (C. W.).*

CASE-HISTORIES

Case 1.—*A married man, aged 36, was admitted to hospital in January, 1915, as a case of acute appendicitis. He gave a history of right-sided abdominal pain which had started quite suddenly 24 hours before admission. Temperature 100°F; pulse-rate, 92; respirations, 30. Examination showed considerable guarding over the right iliac fossa, and a small lump could be palpated. Operation was performed an hour after admission, through a muscle-splitting incision over the right iliac fossa. There was some bloodstained free fluid inside the abdomen. On lifting the cæcum out of the abdominal cavity a large gangrenous appendix epiploica was seen on the outer side of the cæcum. The appendix vermiformis was normal and overhung the pelvic brim. The gangrenous fatty lump was excised and its attachment to the cæcum invaginated with a purse-string suture. The vermiform appendix was also removed. The patient made an uneventful recovery.*

Case 2.—*A married woman, aged 39, was admitted in June, 1921, complaining of acute abdominal pain and vomiting. The pain had commenced after she had passed a constipated motion. On admission she was acutely ill. T., 99; P., 120; R., 32. There was considerable guarding of the lower quadrants of the abdomen. Per vaginam there was some tenderness in the posterior fornix, and per rectum some tenderness in the upper part of the anterior rectal wall. The diagnosis of torsion of the left ovary was made. A laparotomy was performed through a midline incision and a gangrenous appendix epiploica was found on the lower part of the sigmoid colon; it was excised. Recovery was uneventful.*

Case 3.—*A boy, aged 19, was admitted in 1929 complaining of acute abdominal pain, of 48 hours' duration, limited to the right iliac fossa. Appendicectomy had been performed 3 years before admission. T., 99·8; P., 96; R., 28. There was definite tenderness and guarding over the right iliac fossa. As the appendix vermiformis had been removed previously it was decided to watch the patient for 12 hours. There was a leucocytosis of 18,000 by the following day and the temperature had risen to 101°. Operation was decided upon. The old operation scar was excised and the abdomen opened over the*

1 included all those with healthy gums, class 3 with advanced gingival disease, and class 2 those gingival state was moderately satisfactory. In assification no account was taken of the presence tal caries.

the extractions were carried out under general esia with nitrous oxide and oxygen, occasionally mented by trichlorethylene. The first blood e was taken as soon as the patient was unconscious. ecessary extractions were then performed, usually ntal students under the supervision of the dental n in attendance. Immediately after the last tooth een withdrawn, and while the patient was still scious, a second blood sample was taken. No pt was made, by subsequent blood-cultures, to ine the duration of bacteræmia.

specimen of blood consisted of 10 ml. and was distri- immediately as follows: (1) 4 ml. into 50 ml. of 0·15% broth containing 0·3% sodium citrate; (2) 2 ml. ml. of 1% sodium citrate; and (3) the remainder into sterile bottle from which serum was separated for other ations.

return to the laboratory 1 ml. of citrated blood was with 12 ml. of melted agar and poured into a petri r quantitative estimation of the intensity of bacteræmia. mainder was added to a bottle of Robertson's meat-medium.

r 24 hours' incubation in glucose broth at 37°C, was usually visible in the form of discrete clumps surface of the blood-cells, which had settled into an even at the bottom of the bottle. Occasionally growth was from the start—most often when the quantitative was high. Subcultures were made on 5% horse-blood- lates incubated aerobically, and representative colonies picked off and examined in pure culture.

II—RELATION BETWEEN NUMBER OF TEETH EXTRACTED AND INCIDENCE OF STREPTOCOCCAL BACTERÆMIA

al ory	0–5 teeth extracted		6–10 teeth extracted		11 or more teeth extracted	
	Total no. of patients	No. and per-centage positive	Total no. of patients	No. and per-centage positive	Total no. of patients	No. and per-centage positive
1	34	11 (29·4%)	11	7 (63·4%)	6	5 (83·3%)
2	20	7 (28·5%)	24	10 (41·7%)	60	40 (66·6%)
3	2	Nil	14	6 (43·6%)	29	22 (78·5%)
..	56	18 (32·1%)	49	23 (46·9%)	95	67 (70·5%)

tures in Robertson's meat were examined by gram- d smears, and were subcultured anaerobically on horse-agar plates. Any streptococci isolated from anaerobic es were tested for their ability to grow aerobically. trictly anaerobic streptococci were found, though a er of other strict anaerobes were encountered.

RESULTS

ch of us independently investigated 100 patients r similar conditions, with results which were rally comparable and have been combined in the wing analysis.

ith one exception—where a diphtheroid was ered—all preoperative specimens were sterile. ng into account all types of organisms, positive operative cultures were obtained in 113 (56·5%) e 200 cases. Streptococci predominated. and were ered from 108 (54%); diphtheroids were grown 5, and obligatory anaerobic gram-negative cocci 6. Several patients had mixed infections, either of rent organisms or of different strains of streptococci. classification of streptococci in dental bacteræmia cussed in another paper (Porterfield 1949).

Diphtheroids are often regarded as contaminants in blood-cultures, but in this investigation it is probably justifiable to regard them as having originated in the mouth. Their frequency in the oral cavity, together with the fact that in several cultures they were mixed with streptococci, supports this view, which is shared by Okell and Elliott (1935) and Hirsh et al. (1948).

The anaerobic gram-negative cocci were found in 6 patients in the second hundred investigated, and were identified as *Veillonella gazogenes* (Bergey 1948). Hall and Howitt (1925) recovered this organism from normal saliva, so its presence in the blood-stream after dental extractions need occasion no surprise. It was probably present in some of the first hundred cultures, but at that time its significance was not appreciated.

TABLE III—RELATION BETWEEN INCIDENCE OF BACTERÆMIA AND DURATION OF OPERATION

Dental category	Duration of operation			All times
	0–5 min.	6–10 min.	11 + min.	
Class 1 ..	2 out of 6	2 out of 2	1 out of 1	5 out of 9
Class 2 ..	6 ,, ,, 13	3 ,, ,, 4	3 ,, ,, 3	12 ,, ,, 20
Class 3 ..	3 ,, ,, 5	0 ,, ,, 0	3 ,, ,, 3	6 ,, ,, 8
All ..	11 ,, ,, 24	5 ,, ,, 6	7 ,, ,, 7	23 ,, ,, 37

Table I shows the relation between the condition of the patients' gums and the incidence of streptococcal bacteræmia. Positive postoperative cultures were obtained from 45·1% of patients in class 1, from 54·8% in class 2, and from 68·8% in class 3. This apparent increase in the incidence of bacteræmia with increasing severity of gum disease conforms with the findings of Okell and Elliot (1935), who used a similar method of classification. However, since patients with badly diseased gums generally required multiple extractions, whereas those with healthy gums received less extensive treatment, it seemed possible that these figures might be misleading. The frequency of positive cultures was therefore related to the number of teeth extracted, and the results are presented in table II. When five or fewer teeth were removed, 32·1% of the postoperative cultures were positive; with removal of six to ten teeth, 46·9% were positive; and with removal of eleven or more teeth, 70·5% were positive. Moreover, when these figures were subdivided according to the state of the gums, it became clear that bacteræmia was no more likely to arise in a patient in class 3 than in a patient in class 1 who was subjected to the same number of extractions.

Another factor which seemed likely to influence the incidence of bacteræmia was the duration of the operation. This was recorded in 37 patients, and the results are presented in table III. The column on the right shows that, as in the whole series, there are more positive cultures in class 2 than class 1, and more in class 3 than class 2. The incidence of bacteræmia is related to the duration of the operation (without regard to the dental class) in the last line of the table. When the procedure lasted five minutes or less, 11 out of 24 postoperative

TABLE IV—RECOVERY OF *Chr. prodigiosum* FROM BLOOD-CULTURES AFTER APPLICATION OF THAT ORGANISM TO GUMS IMMEDIATELY PRIOR TO EXTRACTIONS

Dental category	Total no. of patients	Number and percentage positive

Class 2	16	7 (43·7%)
Class 3	5	2 (40·0%)
All	29	12 (41·4%)

If an appendix epiploica is lying within a hernial sac it may undergo torsion within the sac. If adherent to or wrapped round an inflamed appendix vermiformis or diverticulum, an appendix epiploica will share in the inflammatory process.

More than one appendix epiploica may be involved (Hunt 1919, Pines et al. 1941).

CLINICAL PICTURE

We are not concerned with cases in which appendices epiploicæ become secondarily involved in disease, nor with those cases showing no acute manifestations.

Hunt (1919) described the incidental finding of a strangulated appendix epiploica in the absence of any symptoms and signs. It is quite probable that a certain number of cases with complaint of unexplained mild attacks of abdominal pain are due to subacute or chronic torsion of appendices epiploicæ (Moore 1940).

The condition is most commonly seen between the ages of 20 and 60; men and women are equally affected. Often there is a history of previous attacks of abdominal pain. The current attack has lasted from a few hours up to 6 or 8 days. Abdominal pain is the chief complaint. It may be sudden or gradual in onset, and is described as aching, sharp, or colicky. The site of the pain varies with the site of the affected appendage. The sigmoid colon is the most common site, and pain is most often referred in these cases to the left iliac fossa, but may spread centrally, and occasionally to the right side. Torsion of appendages of the cæcum, the next most common site, give rise to pain in the right iliac fossa. If a strangulated appendix epiploica is lying in the pelvis, pain is experienced in the lower abdomen.

The patient is usually not acutely ill. There is some fever, 99–101°F. The pulse and respiration rates are raised. Nausea and vomiting may both occur but are more often absent. Appetite and bowels are usually unaffected. In some of the more severe cases there is a polymorphonuclear leucocytosis.

Examination of the abdomen reveals signs dependent upon the site of the strangulated appendage. There is no generalised rigidity, but guarding of varying degree can be detected over the affected area. Marked local tenderness is found over the strangulated appendix epiploica, and there may be rebound tenderness. Pines et al. (1941) noted hyperæsthesia of the skin. In some cases a mass may be felt in the abdomen. In cases with strangulated appendices epiploicæ lying in the pelvis, examination of the pelvis per rectum will reveal tenderness, and sometimes a mass.

An appendix epiploica which undergoes torsion within a hernial sac will give the signs of a strangulated hernia. Cases in which an appendage has formed a band, and in which a loop of bowel has become obstructed will exhibit the signs of intestinal obstruction.

DIFFERENTIAL DIAGNOSIS

There are no pathognomonic features of torsion of an appendix epiploica on which a diagnosis can be made preoperatively. When torsion occurs in a cæcal appendage and an appendicectomy has been performed previously, the diagnosis may be made tentatively; Babcock did so in one case (Fiske 1936), and this diagnosis was suggested in one of our cases (no. 3).

The commonest diagnosis made before operation is acute or subacute appendicitis. Pines et al. (1941) point out that a differential feature is the disproportion between abdominal tenderness, the duration of symptoms, and abdominal rigidity in torsion of an appendage.

Sigmoiditis, diverticulitis, cholecystitis, torsion of ovarian cyst, degeneration in fibromyoma, strangulated hernia, neoplasm of bowel, intestinal obstruction, and mesenteric thrombosis are the other preoperative diagnoses which are made.

TREATMENT

Treatment is excision of the strangulated ap epiploica.

SUMMARY

Eight cases of torsion of appendix epiploica rise to acute abdominal symptoms are added to six previously reported.

The anatomy, function, and surgical signific appendices epiploicæ are discussed.

The clinical features and differential diagn torsion of appendices epiploicæ are described.

The treatment is excision of the strangulated appendage.

BACTERÆMIA FOLLOWING DENTA EXTRACTIONS

M. G. McEntegart
M.D. Lpool

J. S. Porterfi
M.B. Lpool

From the Department of Bacteriology, University of Liv

Transient invasion of the blood-stream by ba from the mouth as a result of dental extractions wa demonstrated by Okell and Elliott (1935), who that 60·9% of 138 people subjected to dental extra under general anæsthesia subsequently had a st coccal bacteræmia. Later Elliott (1939) showed mere rocking of the teeth with dental forceps in streptococcal bacteræmia in 18 out of 21 patients severe gum disease and in no less than 5 out of 20 pa without detectable gum disease.

Burket and Burn (1937) found positive cu in 17% of patients after extractions under local thesia, and a similar proportion was reported by P and Kempf (1939). Few accounts record such a incidence as that reported by Okell and Elliott.

METHOD

The following observations, made at the Liv *Dental Hospital, form part of an investigation* in pathogenisis of subacute bacterial endocarditis.

After having their mouths inspected in one de ment, those patients needing extractions were not to take any solid food after 10 P.M. and to r to the extraction department the next morning. E tionally teeth might be removed on the day of attendance when some condition, such as acute a abscess, made immediate treatment desirable.

After the purpose of the experiment had been expla and permission to take blood granted, the conditi *the patient's gums was assessed in one of three categ* by the dental surgeon in charge of the extraction-r

at the age of 1–7 years with that of their siblings. ound that by the age of 4 or 5 years the premature had fully caught up with the physical development of l-term child. Girls reached the normal weight earlier oys. The smaller the birth weight the slower the gain in weight and, to a lesser extent, in height.

me (1944) states that a baby weighing 5 lb. at birth ch a normal stature by the age of 4 or 5 years, whereas weighing 4 lb. or under at birth will always be small. e (1946) says that the physical development of prema- abies is relatively slow during "the first years of life," fter this it becomes normal, though some children below the average in weight and height. She does e figures, however, to support this statement.

ne and Gordon (1942) claim that premature birth has nificant effect on physical development, provided that e of the infant is reckoned from the date of conception. pö (cited by Dunham 1948) concludes that the growth emature infant usually shows a well-marked disturbance first 3–5 years of its life, and thereafter is normal. maller the baby at birth the more the weight and height hind the normal. He ascribes this defect to rickets and nutrition.

mmerer (1908) notes that children of small birth weight lag behind those of normal birth weight for many years. f his charts shows a difference of 6 lb. at the age of rs.

pper (1928) studied the growth of 62 premature boys 9 premature girls. He found that they had a sub- al weight even at the age of 14 or 15. The smaller the t at birth the longer the subnormality persisted. The were further below the normal weight than the girls, as the girls tended to be further below the normal t. Most of the children were of the asthenic type a long trunk, thin arms and legs, little fat, and poor lature.

n Sydow (1936) found underdevelopment in 99 premature en whom he examined at the age of 3–9 years. Forschner- (1924) and Brander (1941) found similar retardation. r (1946) found 217 premature babies underweight at the f 1–6 years.

llien (1948) found that the average weight at any given ses steadily with the birth weight. She found an average ence of 2 lb. at the age of 2 years between the children smallest birth weight (4 lb. 8 oz. or less) and those of a birth weight (8 lb. 9 oz. or more). At the age of 3 years ifference was 6 lb., and at 4 years it was 7 lb.

en and Blumberg (1948), in an investigation of 40 cases explained dwarfism in Boston, showed that the dwarfs a birth weight averaging 1·1 lb. below that of normal en. There was a positive correlation between birth t and subsequent thinness.

Dunham (1948), in a very complete review of prematurity, sums up by saying: "It must be admitted that no entirely satisfactory norms for the growth of premature infants have been established. Additional data need to be collected in order to answer the primary question of the expected rate of growth of a premature infant of a given birth weight from birth to the period at which the infant may be considered mature."

From the experimental work in animals reviewed by Huggett (1946) it might certainly be thought likely that birth weight would influence subsequent growth. Marshak (1936) demonstrated this in rats.

Still less has been written about the subsequent physical development of children who had a large birth weight. Gray and Eder (1941) compared the physical development in later childhood of 12 children who had weighed at birth more than 8 lb. 13 oz. with that of 12 normal controls, and found that those who had been large babies were heavier. Mossberg (1948), in an investigation of obesity in childhood, found that there was a tendency to a large birth weight in the children studied.

PRESENT STUDY

The present study was based on the maternity and child-welfare and school medical service records of children in Sheffield and an adjacent area of the West Riding of Yorkshire.

The investigation covers all children born between 1935 and 1943 whose records could be obtained and who fell into one of the following birth-weight groups:

(A) 5 lb. 8 oz. or less.
(B) 7 lb. 2 oz.–7 lb. 6 oz.
(C) 8 lb. 8 oz.–9 lb. 8 oz.
(D) 9 lb. 9 oz. or more

There were 517 children in group A (207 boys, 310 girls), 712 in group B (364 boys, 348 girls), 940 in group C (530 boys, 410 girls), and 257 in group D (163 boys, 94 girls). Twins were included in the series. It was impossible to subdivide group A further, because of the few records available for children who had been very small premature babies.

The birth weights of children born on the district were obtained from the midwives' antenatal charts, and of those born in hospital either direct from the hospital or from the infant-welfare charts. The birth weight is obtained for the latter from a note brought by the cultures were positive; when the time was more than five minutes, 12 out of 13 were positive. The numbers in each group are small, but the results support the view that the duration of the operation is more important than the state of the patient's gums in determining the incidence of bacteræmia.

In 29 instances a suspension of a non-pathogenic organism *Chromobacterium prodigiosum* (*Serratia marcescens*) was applied to the gums immediately before teeth were extracted, as in the experiments of Burket and Burn (1937). Blood-samples were cultured in the usual way, and were examined for the presence of *Chr. prodigiosum.* The results are presented in table IV. The indicator organism was recovered from 12 patients (41·4%); there is no apparent relation to the dental category, but the numbers are too small to be significant.

Quantitative counts showed the intensity of bacteræmia to be low. More than two-thirds of all counts were below 10 colonies per ml. blood, and only 6 were above 25 colonies per ml. In subacute bacterial endocarditis the intensity ranges commonly from 20 to 200 colonies per ml., although it may range from less than 1 to over 1000. It was not possible to relate the intensity of the bacteræmia to the dental category of the patient or to the number of teeth extracted.

DISCUSSION

Okell and Elliott (1935) related the incidence of bacteræmia to the degree of oral sepsis; Burket and Burn (1937) considered that both oral sepsis and the amount of operative trauma were significant; Hirsh et al. (1948) were unable to correlate the incidence of bacteræmia with age, sex, race, state of oral hygiene, or number of teeth extracted, but reported that the more extensive the surgical procedure the greater was the number of positive cultures. Analysis of our results shows that the apparent relation of the incidence of bacteræmia to the extent of oral sepsis is illusory, but that the number of positive cultures is proportional to the amount of trauma as indicated by the number of teeth extracted and by the duration of the operative procedure. The experiments in which *Chr. prodigiosum* was employed indicate that any organism applied to the gum margin may enter the blood-stream as a result of dental extractions, irrespective of the severity of infection prevailing in the mouth.

The finding of *Veillonella gazogenes* in blood-cultures from 6% of normal people is of interest since this organism has been reported as a cause of subacute bacterial endocarditis (Loewe et al. 1946). This organism was never recovered by the usual technique of blood-culture in bottles of nutrient broth; and possibly attention to anaerobic methods might reveal this organism as the cause of other infections and might explain certain cases of subacute bacterial endocarditis in which the clinical picture is characteristic but repeated blood-cultures are reported as negative.

Prophylactic sulphonamides or penicillin have been recommended for patients with congenital or rheumatic heart-disease who require dental treatment. These agents cannot be expected to prevent bacteræmia, since this is a mechanical phenomenon; and claims that they have this effect have usually been due to failure to neutralise the circulating agent by the addition of *p*-aminobenzoic acid or penicillinase to the culture-medium. When adequate methods have been employed, as by Hirsh et al. (1948), a slight but significant reduction in the incidence of streptococcal bacteræmia (from 34 to 15% by Hirsh et al.) has been noted. These workers suggest that penicillin may act by reducing the number of organisms in the gums and also by preventing the multiplication of those which do enter the blood-stream. They recommend the administration of 300,000 units of penicillin in wax and oil twenty-four hours prior to extractions, supplemented by a further 600,000 units of the same preparation three to fo before the operation.

SUMMARY

Blood-cultures taken from 200 patients imm after dental extractions under general anæsthesia streptococcal bacteræmia in 54%. The incid bacteræmia was unrelated to the extent of oral but was related to the trauma of the operation cated by the number of teeth removed and the d of the operation.

In addition to streptococci and diphtheroids, o anaerobic gram-negative cocci identified as V *gazogenes* were recovered from 6 out of 100 of blood-cultures.

We wish to thank Prof. H. H. Stones for his k granting facilities for this work at the Liverpool Hospital; and also Mr. H. E. Ballance, Mr. F. E. Lawt Mr. E. Wynn Davies who supervised the extract assessed the dental condition of each patient.

ONE of us (R. S. I.) observed, in the outpatient de ment of the Hospital for Sick Children, Great Or Street, London, that a notable proportion of chi who were below the average weight had been babies at birth. This led to a study (Illingworth in which the weights at various ages of 150 children at birth weighed $5^{1}/_{2}$ lb. or less were compared wit weights of 150 consecutive children who at birth wei $8^{1}/_{2}$ lb. or more. In these London children there w considerable difference between the two groups a ages, those who had been small at birth lagging behind those who had been heavy babies at b Thanks to the coöperation of Dr. H. M. Cohen, school medical officer in Sheffield, and Dr. A. B the principal maternity and child-welfare office making their records available for study, this work now been amplified and confirmed.

There are relatively few published references to relation of weight at birth to subsequent phy development.

Hess and Chamberlain (1927) and Hess and Lundeen (state that premature* infants can be made to reach a no weight if supplementary feeding is maintained for four y Hess and others (1934) compared the growth of 250 prema

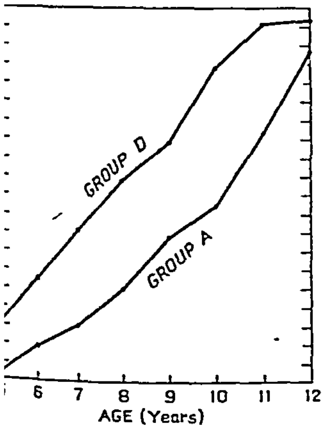
---

* A baby is said to be premature if it weighs 5 lb. 8 oz. or l birth, irrespective of the duration of gestation.

; C and D fell into this category. At the age of years 15·7% of 140 children in group A were below the average weight, compared with 1% of ildren in group B, 1·1% of 279 children in group C, 3% of 76 children in group D.

differences in height in the four groups are less inced but nevertheless definite. Tables III and IV that there was a difference of about 2–6 cm. in ight at all ages between children of small birth and those of large birth weight.

e the difference in height was less than the nce in weight, it follows that the weight/height vas greater for children of large birth weight than ose of small birth weight. Weight at birth is ore distinctly related to the status of a child as determined by such methods as the Wetzel grid and Tuxford index, which are based on the weight/height ratio. Wetzel (1948) has given a full review of his grid technique.



Growth curves of girls (data as for boys in fig. 1).

When the weight and height of children of different birth-weight groups are plotted on the Wetzel grid, it is found that children of group A fall considerably those of group D in "developmental level" and to r extent in physique. The "developmental level" id by plotting weight and height against age, and hysique by plotting weight against height. The pmental levels are arranged in percentiles. A plot- 1 the 80th percentile implies that 80% of children a developmental level which is superior to his. igures for all 70 children in group A at the age years and for all the 41 children in group D same age were plotted on the grid; 25·1% of A and 78% of group D fell above the 67th or "normal" percentile, whereas 4·8% of group D and 34·3% of group A fell below the 82nd percentile, 17·1% of group A being so far below the average that they fell below the 98th percentile.

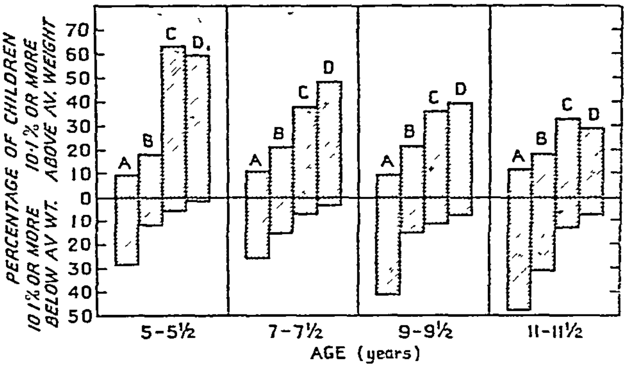


Fig. 3—Summary of table V, showing relation of birth weight to subnormal and supernormal weight in later childhood: A, birth weight 5 lb. 8 oz. or less; B, birth weight from 7 lb. 2 oz. to 7 lb. 6 oz.; C, birth weight from 8 lb. 8 oz. to 9 lb. 8 oz.; D, birth weight 9 lb. 9 oz. or more.

Another method of assessing nutritional status was described by Tuxford (1917, 1942), who devised a formula from the weights and heights of London elementary school-children which gives the optimal ratio of weight to height at various ages. The index for London school-children in 1938 was 1. The formula necessitates a simple calculation for each child, and Campbell and Weir (1948) devised a nomogram from which Tuxford's index can be obtained in a few seconds. For the purposes of this study the age of 7 years was chosen at random, and the mean was obtained for children in each birth-weight group. The mean indices were as follows:

	Weight at birth	*Total no. of children (both sexes)*	*Mean Tuxford index*
Group A:	5 lb. 8 oz. or less	54	0·95
Group B:	from 7 lb. 2 oz. to 7 lb. 6 oz.	120	1·00
Group C:	from 8 lb. 8 oz. to 9 lb. 8 oz.	129	1·04
Group D:	9 lb. 9 oz. or more	40	1·10

Both Tuxford and Wetzel emphasise that the chief value of their methods lies in the study of the pattern of a child's growth rather than in isolated readings. Since the birth weight is related to the weight and height in the same way throughout childhood, it follows

ABLE V—RELATION OF BIRTH WEIGHT TO SUBNORMAL AND SUPERNORMAL WEIGHT IN LATER CHILDHOOD (BOTH SEXES)

mother from the hospital to the child-welfare centre. It was realised that the mother's memory of the birth weight of her child, a few years after it had been born, would be inaccurate. When 110 mothers were asked to give the birth weight of their babies born five years previously in a maternity hospital, in which we had accurate records of the birth weight, 83·9% knew the birth weight correctly to within 4 oz., but 10·4% made an error of over 8 oz. It was therefore clear that no investigation dependent on the mothers' memory of birth weights would be accurate.

The weights and heights in later childhood are those recorded by the child-welfare and school medical officers.

It is fully realised that there may be inaccuracies in the figures recorded for weight at birth and for the weight and height in later childhood. The essential point, however, is that the errors would apply equally to all four birth-weight groups and would therefore not be significant. Records show, as one would expect, that the birth-weight groups were scattered approximately evenly through the various schools.

RESULTS

Tables I–IV show the mean weights and heights at various ages of children belonging to the four birth-weight groups studied, and figs. 1 and 2 show the curves of groups A and D from the age of 5 that of 12 years. The total number of children in gated has already been given. In many cases records showed the weights and heights of child intervals of two or three years. All these figures been utilised for working out the means given.

TABLE IV—RELATION OF BIRTH WEIGHT TO SUBSEQUENT HEIGHT IN GIRLS

Age (years)	Group D : birth weight 9 lb. 9 oz. (4337 g.) or more		Group C : birth weight from 8 lb. 8 oz. (3856 g.) to 9 lb. 8 oz. (4309 g.)		Group B : birth weight from 7 lb. 2 oz. (3238 g.) to 7 lb. 6 oz. (3351 g.)		Group A : birth weight 5 lb. 8 oz. (2495 g.) or less

10	15	133·6	54	134·8	51	133·8	30	128·5
10½	10	136·6	59	136·6	33	138·2	34	133·0
11	11	140·9	53	141·9	29	138·3	27	134·5
11½	6	144·0	29	141·4	19	139·9	20	140·2
12	6	144·3	31	145·7	15	146·2	16	139·8
12½	4	154·1	18	147·7	11	146·3	19	145·3
13	5	147·8	10	150·9	7	150·0	8	146·0

It will be seen that, with a very occasional exc due to the fact that there were two few children in groups to make the mean figure reliable, there constant uniform gradation of weight from that children who at birth weighed 5 lb. 8 oz. or less to of the children who at birth weighed 9 lb. 9 oz. or At the age of 5 years, for instance, there was a di in boys of 2·4 kg. (5·3 lb.) between the two 2·3 kg. (5·1 lb.) at the age of 7 years ; 3·9 kg. (8 at the age of 9 years ; 7·1 kg. (15·6 lb.) at the 11 years ; and 2·9 kg. (6·4 lb.) at the age of 12 y In girls there was a difference of 2·7 kg. (5·9 lb.) at age of 5 years ; 5·1 kg. (11·2 lb.) at the age of 7 y 5 kg. (11 lb.) at the age of 9 years ; and 5·8 kg. (12 at the age of 11 years. The figures for the child groups B and C in almost all cases fell between means. In general the difference was greater for than for boys. The tables show that a girl aged 7 y from group A weighs the same as a girl aged 5 y from group D. A girl aged 10 years from group weighs the same as a girl aged 7½–8 years from gro There can therefore be no doubt that in these chil there was a definite and important connexion be weight at birth and weight in later childhood.

Table v, which is summarised in fig. 3, shows relation of birth weight to subsequent weight in a more striking manner. The table shows the range of variation in weight of children of the four birth-weight groups. The figures used for the "normal" weight and height are those given by Paterson (1947). They correspond extremely closely to those given by the school medical officer for London elementary schoolchildren (London County Council 1940).

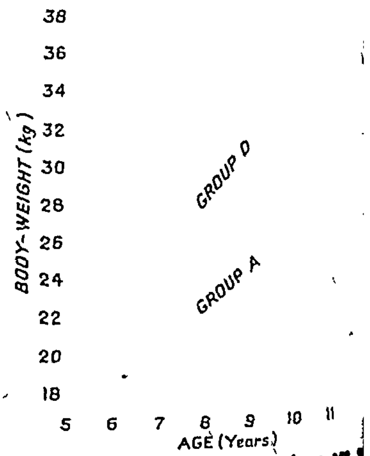

Fig. 1—Growth curves of boys from age 5 years to that of 12 years : group A, bir weight 5 lb. 8 oz. (2495 g.) or less ; gro D, birth weight 9 lb. 9 oz. (4337 g.) or mor

It will be seen that 9·5% of 232 children in group A and 59·2% of 120 children in group D were 10% or mor above the "normal" weight at the age of 5–5½ years the corresponding figures at the age of 7–7½ year were 10·4% and 48·0%. On the other hand, 28·9% o group A were 10% or more below the "normal" weight compared with 1·7% of group D. The corresponding figures for 9–9½ years were 41·4% and 7·8%, and for 11–11½ years 47·4% and 7·1%.

The table also shows a striking difference in th percentage of children of the four birth-weight group who were still further below the average weight—20 1% or more below the normal for the age. At the age o 7–7½ years 11·1% of 134 children in group A and 2 4% of 247 children in group B were 20·1% or more below the average weight, whereas none of the 341 children o

ADIOTHERAPY OF ACCESSIBLE GNANT TUMOURS BY ALTERNATING CHESS-BOARD METHOD

uniform distribution of the administered dose ation throughout the treated volume of tissues is pted and professed aim in almost every method otherapy of malignant growths. The concept ial homogeneity dates from about 1904, when er suggested the increased target-skin distance ain a distribution in depth similar to that on face which was effective in dermatological con- treated with röntgen rays (Dessauer 1923). as an epoch of pioneering in radiotherapy, when introduced filtration by covering the patient sheet of aluminium, and when in 1905 Köhler rxheimer (quoted by Wetterer 1919), on the basis ir histological examination, stated "that no ative changes as an effect of röntgen irradiation be detected in tumours at a depth greater than from the surface, and that the review of the re did not show the existence at that time of ord of effect at a depth over 6–8 mm."

since Dessauer's enunciation of spatial homo- as the aim of proper deep X-ray therapy the le of uniform distribution of radiation has ccasionally been questioned (Holzknecht 1924, ian and Mayneord 1943).

concept of selective radiosensitivity of malignant g cells which permits the delivery of a "canceri- dose of radiation with avoidance of irreversible to normal structures seems the only relevant al reason for uniform distribution in planning ent.

attainment of high dose levels is still the main e in almost every method of treatment, and tention is paid to the preservation of connective-tissue structures, which is, however, as important as the delivery of an effective dose of radiation.

The effect of ionising radiation on malignant cells is not the whole story of the events leading to the disappearance of the tumour and eventual cure; many other factors come into play, of which the stroma reaction and the resistance of the host to the tumour are of great importance.

On the physical side the question of exact dose assessment necessitates the repetition, in the treated region of the body, of physical conditions corresponding to those *obtained in a laboratory phantom.*

Broadly speaking, attempts are being made with the present methods of treatment of a patient with a malignant tumour to obtain a uniform distribution of radiation throughout the volume of treated tissues, so as to be able, if it proves successful, to repeat the same type of treatment in another patient.

In practice, homogeneous distribution of denaturing radiation is attained only to some degree in deep X-ray therapy, whereas in interstitial radium therapy, which is successful in numerous cases, homogeneous distribution is never achieved.

A successful attempt to disprove that spatial homogeneity of radiation is essential for an effective treatment, and a new method which is a complete departure from all the existing methods in use in both fundamentals and technical details, are here described.

The principle of the method is that, with a lead chess-board sieve, portions of the tumour 1 cm. square are exposed to radiations, while other portions of similar area are protected so that important structures remain undamaged and can take part in repair. After a suitable period of treatment another chess-board sieve, in which the order of opaque and transparent areas is reversed, is used, and the previously untreated areas are exposed, while the already treated areas are protected and their recovery not hindered.

MATERIAL AND METHOD

Tumours of breast and skin and secondary glands of the neck were treated. Patients with very advanced inoperable tumours of breast in which only some palliative treatment could be given, or with tumours of skin which, because of their extent, situation, and infiltration of surrounding and underlying structures, or because of the general condition of the patient, was unsuitable for radical radiotherapy or surgery, were treated by the sieve method.

The radiation was delivered through a lead sieve with circular or square apertures 1 or 2 cm. in diameter. Ultimately a chess-board arrangement with alternate opaque and transparent squares was found most suitable (fig. 1).

The chess-board is applied tightly over the part to be treated, and the periphery of the lead mask is marked on the skin, as also are the centres of the apertures. This is most important to secure landmarks for appropriate exposure of parts which have to be irradiated and to shield the areas to be screened from the beam during treatments taking place over weeks.

In tumours of the skin always, and in breast tumours whenever possible, a specially moulded applicator is built for each case (fig. 2). A stent impression of the lesion is made in a plaster cast, over which a tightly fitting stent or black-tray dental-compound applicator is built in such a way as to be easily mounted over the part of the body, and fitting in such a way as not to allow even minimal shifts of the applicator which might allow the transposition of the transparent and opaque portions of the lead chess-board, which is recessed in the mould.

The radiation has to be delivered at right angles with the X-ray tube head applicator directed vertically. To

that the growth curves of children who were small babies at birth are likely to be well below those of children who were large babies.

DISCUSSION

It is clear that in a considerable number of children there is a close relationship between weight at birth and subsequent physical development. This study, however, leaves many questions unanswered. An analysis of body build in various birth-weight groups is necessary, and this is now being carried out on the children whose records were used for this investigation.

It would be interesting to know what rôle, if any, maternal malnutrition had in the causation of prematurity in the children of the smallest birth-weight group. That malnutrition in pregnancy has an adverse effect on the birth weight has been shown in both man and animals. Smith (1947), for instance, showed that in the Netherlands during the German occupation from 1944 to 1945 there was a positive correlation between the nutritional status of the mother in the last three months of pregnancy and the weight of the fœtus at birth. Huggett (1946) reviewed the evidence for similar findings in animals. It would be of great interest if it could be shown whether there is any relationship between maternal nutrition, because of its effect on birth weight, and the subsequent physical development of the offspring. Wallace (1945) showed that fœtuses born of ill-nourished dams weighed less than half those of well-fed ones. Some tissues were more affected than others, nerve tissue competing for the available nutrients more effectively than bone, and bone more effectively than muscle or fat. Malnutrition of the dam altered the whole build of the fœtus ; the fœtus was not a mere miniature version of the larger fœtus of the same age. It seems likely, however, that maternal malnutrition is only one of many factors in the causation of prematurity in this country. As Dunham (1948) says, the cause of prematurity is in most cases unknown.

The suggestion made by Hess and Chamberlain (1927) that premature infants can be made to reach a normal weight by proper feeding is of great interest and needs to be confirmed. There is some experimental evidence that malnutrition in the early days of life may have a permanent effect on development. Hammond (1932) showed that in sheep after birth different parts of the body have different ages of optimal growth. Bone grows first, then muscle, then fat. If lambs are undernourished and are then given an optimum diet, the recuperative powers are limited mainly to those tissues growing mostly in the later period. McMeekan (1940) found the same in pigs. McMeekan and Hammond (1940) have shown that the effect on bodily proportion may be permanent. McCay et al. (1935) retarded the growth of rats by dietary insufficiency for long periods and then gave them an optimum diet. The rats did not catch up to the normal body proportions, and throughout their life (which was longer than that of the controls) they had a smaller body, smaller organs, and smaller bones than normal. The female rats fared worse than the male. Perhaps adequate correction of rickets and anæmia in premature infants would enable them to catch up to the normal weight and height ; but we have not found any positive or negative evidence on this point in published reports. If it were so, it would be of the greatest importance, since it would affect physical development throughout the whole of childhood.

The regular gradation of weight and height at all ages with rise of birth weight suggests that nutrition in infancy is probably not the factor responsible for these differences. It would be difficult to prove, for instance, that the greater weight at the age of 10 years of the 9 lb. baby than that of the 7 lb. baby was due to better nutrition of the former in infancy. Further studies are required in different areas, rural and urban, to determine whether these differences are general. The obtained in Sheffield certainly correspond with obtained by Illingworth (1939) in London children.

These questions need to be answered before one decide whether the commonly used developmental c of weight and height are really applicable to all chil or whether the additional factor of birth weight sh be taken into consideration. If the differences bet the weight and height of the children in this study not related to malnutrition of the babies of small weight, new charts should be constructed to m possible to assess the normality of development child in relation to his birth weight. Our figures based on far too few children for norms to be esta from them ; but, if the general differences in weight height are as large as we have found in Sheffield London, the factor of birth weight should clearly taken into account in the assessment of a child.

Unfortunately our records do not go far into cence. They give no indication of the onset of pu We feel that the changes associated with puberty the interpretation of the findings in the age-group particularly difficult. We cannot say whether or the differences in weight and height in children of diff birth weights will disappear at puberty.

SUMMARY

To investigate the relation of weight at birth subsequent physical development in later chil we studied the weights and heights at various ages 517 children who at birth weighed 5 lb. 8 oz. or 712 children who at birth weighed from 7 lb. 2 oz. 7 lb. 6 oz., 940 children who at birth weighed 8 lb. 8 oz. to 9 lb. 8 oz., and 257 children who at weighed 9 lb. 9 oz. or more.

At all ages the weight at birth bore a well-marked constant relationship to subsequent physical dev ment. In girls, for instance, there was a difference 11·2 lb. at the age of 7 years between the mean w of children who had weighed 9 lb. 9 oz. or more at and that of children who had weighed 5 lb. 8 oz. or There was a corresponding difference of 11 lb. at age of 9 years and 12·8 lb. at the age of 11 years. average girl aged 10 years who had weighed 5 lb. 8 or less at birth weighed the same as the girl aged 7 years who had weighed 9 lb. 9 oz. or more at At all ages there was a constant gradation in the weight of children of either sex according to birth w

A strikingly high proportion of children of the sm birth weight were far below the "normal" weig later childhood. At the age of 9–$9^1/_2$ years, for inst. 41·4% of the children were 10% or more below "normal" weight, compared with 7·8% of children the largest birth weight. The corresponding figures the age of 11–$11^1/_2$ years were 47·4% and 7·1%. the age of 9–$9^1/_2$ years 15·7% of 140 children of smallest birth weight were 20·1% or more below "normal" weight, compared with about 1% of children of the remaining birth-weight groups.

There were similar but less striking changes in t mean height of these children at all ages. The effect the birth weight on the weight/height ratio is exemplifi by the assessment of these children by the Wetzel gri and Tuxford index.

The possible rôle of nutritional factors is discus and the need for further investigation emphasised.

We wish to thank especially Dr. H. M. Cohen, scho medical officer for Sheffield, and Dr. A. Black, princip maternity and child-welfare officer, for their help, witho which this investigation would have been impossible. We also wish to thank Dr. Fraser Brockington, county medic officer of the West Riding County Council, and his staff, for granting access to their records.

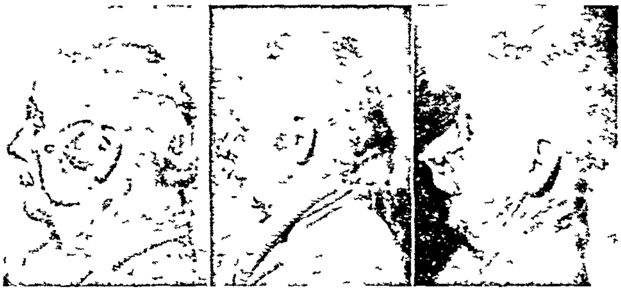
—Case 1: (a) before treatment; (b) at the end of treatment (c) 44 days after the end of treatment.

DISCUSSION

al risk of necrosis would have had to be faced in ing the lesion in case 1, and perhaps also in case 2, urrent methods, and an elaborate arrangement in r radium or X-ray technique would have been d for in an attempt to eradicate the tumour. In irst two cases X-ray treatment only on a protracted could have been used, a radium mould alone being itable because of the thickness of the tumour, an interstitial implant at the base of tumour could be contemplated because of the age and general ition of the patients. In case 3 a radium implant not warranted because of general condition, and only dium mould or routine X-ray treatment was the native to the new method adopted in this case.

ith the new method of treatment the reaction in ree cases was remarkably mild. On no occasion were s of disepithelisation larger than 1 cm. in diameter d. The marginal normal skin and the skin from h the tumour had shrunk away were healing during tment. The amount of residuum, which on histoal examination showed no evidence of viable malig cells, was very small. The cosmetic results in cases d 2 were excellent, and in case 3 just as good as d be expected from any other method.

he disappearance of the tumour coinciding with the of treatment, and the rapid resolution of the residual otic nodule at the site of the lesion in cases 1 and 2, e clinical evidence of the greater ability of the stroma ope with the tumour, and the better absorptive power he inflammatory cell infiltrate to cope with the islands ead cells and other debris.



(a) (b) (c)

Fig. 4.—Case 2: (a) before treatment; (b) at the end of treatment (c) 49 days after the end of treatment.

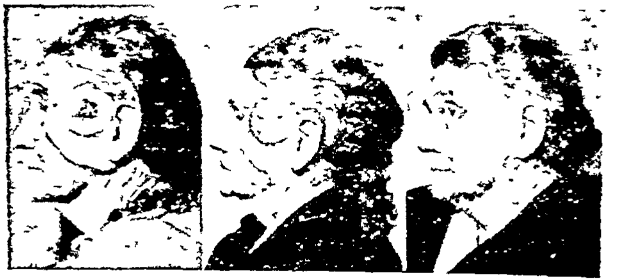
The period of observation after treatment has been very short; but, since the lesions are healed and the histological reports on sections taken at the end of treatment negative as regards viable malignant cells, it is thought that the immediate results are of some interest, and it is not necessary to wait five years to present the survival data of three octogenarians.

The ease with which the apparatus is set up and the availability of an applicator of the size required with a steady mounting were the determining factors in the choice of an X-ray beam generated at 200 kV 12 mA. The doses mentioned refer to 7 cm. and 5 cm. circular areas measured with full back scatter. In fact 20% less was delivered because of the size of the transparent squares. Direct dose-rate readings have proved this estimate to be on the conservative side.

Uniform distribution of radiation in the treated volume of tumour has not been used. In case 1 alternate parts of the tumour received 5000 r while adjoining alternate parts received 3500 r only; in case 2 7250 r was given to one group of squares, 3500 r to others; and in case 3 4500 r was given through chess-board A and 4750 r through chess-board B (the figures represent doses not corrected for size of area).

As stated before, the set-up of the stent or "black-tray" compound mask was such that shifts of the chess-boards in relation to the tumour were reduced to a minimum; but even with the greatest care some shifts are unavoidable, though it is unlikely that they exceeded 1 mm. on either side. However, there may have been a linear overlap, and small strips of tissue may have received the dose given through both chess-boards. This condition would be comparable to that which obtains with interstitial radium implants, where high-dose spots are unavoidable and not detrimental to the outcome of treatment.

The effect of the irradiation through the first series of squares was not confined to the irradiated areas, for the tumour was considerably reduced also in the untreated squares; hence it was unnecessary to give so large a dose to the second series as had been given to the first.



(a) (b) (c)

Fig. 5.—Case 3: (a) before treatment; (b) at the end of treatment; (c) 35 days after the end of treatment.

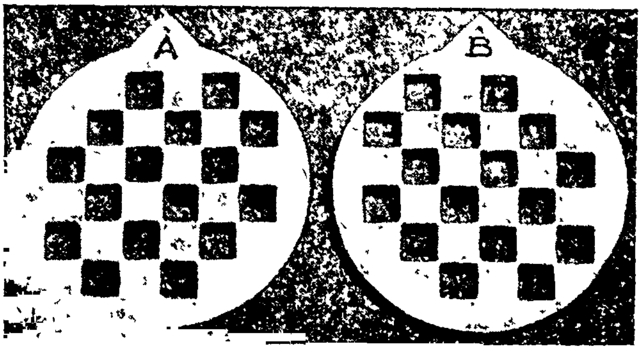


Fig. 1.—Lead chess-board panels. The order of transparent and opaque 1 cm. squares is reversed in the two panels.

avoid oblique penetration into areas beneath the opaque squares the lead chess-board must be in direct touch with the surface of the tumour. In the course of treatment, owing to shrinkage of the tumour, the recess sleeve in the stent mould into which the chess-board is slipped, has to be filed down from time to time.

The thickness of the lead, which is limited for practical considerations, permits 3% of the radiation to pass through on to the protected areas. To that amount of radiation received by the not directly irradiated areas has to be added about 3–5% of scatter radiation from the neighbouring exposed areas. This varies according to the size of the apertures and decreases towards the centre of the " opaque " squares.

The size of the squares has been chosen as not less than 1 cm. because of the results of experiments on the reciprocal vicinity effect of irradiated tissues (Jolles 1949a). This size offered also the best conditions for a histological study of connective-tissue reaction to radiation with the chess-board method (Jolles 1949b).

After a certain amount of radiation has been delivered through this chess-board, a second chess-board is used in which the order of the " transparent " and " opaque " squares is reversed, and radiation is given to sectors of tumours previously shielded. Further treatment may be given again through the first chess-board, and occasionally a fourth series, through the second chess-board, may be found advisable.

The irradiation was given daily for 5 or 6 days a week. The apparatus was set up always by the same people, and every precaution was taken to avoid minimal shifts.

A preliminary group of five cases of advanced carcinoma of the breast, which formed part of the material used for the study of connective-tissue reactions to radiation (Jolles 1949b), and four cases of secondary glands of neck served for orientation and paved the way to building the alternating chess-board technique described here. Three cases of epithelioma of skin treated with the chess-board technique are described in detail.

CASE-RECORDS

Case 1.—A married woman, aged 80, had had for twelve years a slowly growing proliferating ulcerated squamous-celled carcinoma on her left temple 5 × 4 × 2 cm. fixed to the underlying structures. Histological examination showed this to be a squamous-cell carcinoma of the skin. The parenchyma formed infiltrating cords of various thicknesses, the centres of which were undergoing differentiation, of which the degree and extent varied much in different regions. No lymph-nodes were present. The lesion was suitable for a radium mould plus interstitial radium implant at the base of the tumour, or protracted X-ray treatment.

The alternating chess-board technique was adopted and treatment commenced on Nov. 15, 1948. 200 kV 12 mA, 50 cm. F.S.D., 0·5 mm. Cu + 1·0 mm. Al filtration, 1·0 mm. Cu H.V.L., 39 r per min. were the physical factors. The sieve panel was 7 cm. in diameter. 5000 r was given through chess-board A in ten treatments in 11 days, with a 7 cm. diameter circle applicator. At the end of this series the tumour was half its former thickness (4·6 × 3·7 × 1 cm.). Sections were taken before the start of treatment and 2000 r and 4000 r had been delivered through the transp squares in chess-board A. Two days later series B was star 3500 r was given through chess-board B in fourteen ments in 18 days. Sections were taken from exposed protected areas after 2000 r and 3500 r had been given thro chess-board B. The lesion was now about a twentieth of former size.

Deep erythema was noted at the periphery of the area, and small islands of disepithelisation in the 16 days after the end of treatment a small residual nodule 1 cm. in diameter was all that remained of the lesion; 10 days later this was still smaller and a specimen was taken. The pathological report read: tumour cells seen. Fine fibrotic structure." 44 day the end of treatment the skin was smooth, shiny in and with no fibrotic residuum (fig. 3).

The patient subsequently developed a penicillin " with oozing spots on the face, eyelids, auricle, and neck, this soon cleared, and she is now well, with a good no sign of the previous lesion.

Case 2.—A married woman, aged 81, had had rad treatment to a spot on the right cheek when at the age of (32 years ago), and again 15 years ago to a recurrence, 6 years ago she had had a radium capsule applied to a fur recurrence. For four years she had had an ulcer on the side of her face.

Lesion I.—There was an ulcerating proliferating gro on the right cheek, invading the right inner canthus, destro the right side of the nose, invading the cartilage deeply, extending on to the left side of the bridge of the nose. whole thickness of the skin on the right cheek and the eyelid was involved. The lesion measured 6 × 5 This lesion on the right cheek, nose, and eye was palliative lines; 1800 r was given—three treatments hours—and the whole area was cleared by diathermy exci

Lesion II was an ulcerating growth in the left preauricu region, measuring 5·6 × 3·8 × 2 cm.; it was not fix and no glands were involved (fig. 4). Histological examina showed this to be squamous-cell carcinoma of the sk a diffuse anaplastic growth with a very low degree differentiation.

Treatment of this lesion with alternating chess-boards w started on Dec. 2, 1948, and finished on Jan. 13, 1949. 600 was given through chess-board A in twelve treatments 15 days. This was followed by 3500 r through chess-board in fourteen treatments in 18 days. A further 1250 r was giv through chess-board A in five treatments in 5 days. Th total irradiation was 7250 r through chess-board A an 3500 r through chess-board B in treatments spread ov 43 days.

Sections were taken before treatment and from expo and protected areas after 2000 r and 5000 r had been giv through chess-board A. Subsequently sections were taken fro adjoining areas after 2000 r and 3500 r had been deliv through chess-board B and finally after the end of treatm

The regression of the tumour was rapid. The skin reactio was very mild. The areas of disepithelisation did not exce

Fig. 2.—Stent mould fitting tightly with lead sieve in position in th recess sleeve for the X-ray tube applicator.

from sources other than mammalian liver. The ¢, nevertheless, will continue meanwhile to provide nain supply of extracts for general use. It therefore s opportune to record the results of a clinical trial ı extract of whale liver which, given by mouth, ars to be highly effective in the treatment of cious anæmia.

is extract, supplied by United Whalers Ltd., was ıred by a simple process of water extraction and tion. The resultant aqueous extract was a brown us liquid, and it was estimated that 1 oz. of extract lerived from 25 oz. of whole liver.

ne cases of typical addisonian pernicious anæmia been treated with this oral preparation, and the ts are shown in the accompanying table. The trials carried out according to the method prescribed for :al testing of liver extracts by the Association of cal Pathologists of Great Britain in order to obtain ıgle maximum reticulocyte response (Whitby and on 1946). That is to say, suitable cases fulfilling all ıostic criteria were observed for some days before commencement of the test to exclude spontaneous ssion. Sources of hæmatinic principle, such as liver kidneys, were barred from the diet. The liver extract then given in uniform daily amounts in divided doses nouth. Reticulocyte-counts were done daily until eak of the response was clearly passed. Administra- of the extract was thereafter continued in the same amounts, and red-cell and hæmoglobin estimations made at weekly intervals. These observations on ncrease of red cells in response to treatment provided tional information as to the potency of the extract. expected increase in the number of red cells in the two weeks of treatment was calculated by the ula of Della Vida (1942).

ıses 1 and 2 were given a total daily dose of 3 oz. by th, and both responded satisfactorily. In cases 3, 4, ıd 6 the daily dose was reduced to $^1/_2$ oz. (equivalent $2^1/_2$ oz. of whole liver), and good responses were ıned in all but case 5, where the increases in red cells reticulocytes were slightly below the expected figures. 3 responded well in spite of a concurrent severe ary infection, but hæmoglobinisation was delayed ıg to iron deficiency. Cases 7, 8, and 9 were given z. of the extract daily (equivalent to $6^1/_4$ oz. of whole), and satisfactory results were obtained in all three s even with this small dosage. The reticulocyte onse in six of the nine cases reached or exceeded the cted levels calculated by the method of Bethell and lhamer (1933). Of the three patients (cases 1, 5, 6), with a suboptimal reticulocytosis two (cases 1 6) showed a satisfactory increase in red cells after weeks' treatment. This conforms to our experience the rise in erythrocyte-count is often a more satis- ory guide than the maximal reticulocyte response in ssing the effect of liver therapy in pernicious anæmia, cially where small repeated doses are administered. ow-up results are given for cases 8 and 9, who were ıtained on the same dose, showing that complete oration of blood levels could be obtained. In addition the initial diagnostic bone-marrow examinations, nal puncture was repeated about the fourteenth day reatment, and complete reversion to normoblastic hropoiesis was found in all cases.

hese results confirm the observation of Aylward et al. 41) that whale liver contains active hæmopoietic or. Satisfactory and complete hæmatological remis- has been obtained here with daily amounts as small $/_4$ oz. (8 g.) of aqueous extract (equivalent to 200 g. whole whale liver). This is the same as the accepted imal therapeutic dose of whole bovine liver, and it refore seems that whale liver is at least an equally ent source of hæmopoietic factor. The possibility might be considered of using whale liver for the preparation of pharmaceutical liver extracts.

THE EOSINOPHIL LEUCOCYTE, EOSINOPHILIA, AND ALLERGY

A HYPOTHESIS

D. J. DALTON
MEDICAL STUDENT, THE LONDON HOSPITAL

A GENERALLY acceptable explanation of the mechanism of eosinophilia and of the function of the eosinophil leucocyte has yet to be advanced. Perhaps the most widely held view is that the presence of a foreign protein is the specific factor causing eosinophilia, and a rôle of detoxication of these proteins has been attributed to the eosinophil.

EOSINOPHILS IN BLOOD AND TISSUES

Modern textbooks state that eosinophils are more abundant in the tissues than in the blood (Wintrobe 1946, Cowdry 1944, Alexander 1941, Smith and Copenhaver 1948), being found especially in the epithelial linings of the respiratory and gastro-intestinal tracts and in the fluids beneath them. Since the bone-marrow is the source of all eosinophils, the bone-marrow picture should indicate the degree of body eosinophilia as a whole more reliably than does the blood picture. A tissue eosinophilia is often found with little or no blood eosinophilia, but in allergic conditions the bone-marrow picture typically shows increased production of eosinophils (Urbach and Gottlieb 1946).

EOSINOPHILIA AND THE ALLERGIC RESPONSE

There is a considerable amount of evidence that eosinophilia is not a reaction to foreign protein per se but is part of an allergic response which develops only after a second introduction of that foreign protein, and then only if a certain latent period elapses between the first and subsequent introductions. The latent period is the same for both the allergic reaction and eosinophilia.

This has been demonstrated in experiments on guinea-pigs by Campbell and others (1935) and Biggart (1932). Further evidence is afforded by Knott and Pearson (1934), who injected appropriate proteins into sensitised patients and found eosinophilia at the site of reaction. Bezançon and Bernard (1930), reviewing the French published work, concluded that in allergic conditions a local eosinophilia is present at the site of reaction, wherever that is. Many other workers—e.g., Rossle (1914), Berger and Lang (1931), and Schlecht and Schwenker (1912)—agree and local eosinophilia is now accepted as part of the histopathology of allergy (Tuft 1938, Urbach and Gottlieb 1946).

The rôle of histamine in the production of the symptoms of allergy is still disputed, but there seems to be little doubt that its part is considerable, even though it may be only one of several toxic substances released in the allergic reaction. Code (1937, 1939) found that in laboratory animals and in man the eosinophil was the richest source of blood-histamine—in fact the only source positively found.

Eosinophilia can no longer be regarded as merely an incidental accompaniment of the allergic reaction, and I suggest that the eosinophil is an important factor in *causing* the allergic response. The following facts support this suggestion:

(1) Human allergic reactions occur usually at the chief sites of eosinophil concentration ("shock organs").

A chain of events is started in the treated areas, and this stretches out beyond the boundaries of the *irradiated sectors* of tumour. The effective doses required in the chess-board method are of a different order from those in orthodox methods.

Whereas up to now the whole problem of dosage in tumours and of methods of irradiation pivoted on the so-called differential radiosensitivity of the tumour cells, and the skin and normal structures were the main criteria regarding the load to which they could be subjected, with the alternating chess-board technique *the resistance to radiation of the connective-tissue* structures and their recovery rhythm are considered of paramount importance.

The time factor, which in the orthodox methods of treatment is related to the cell-life cycle and to the attainment of the highest tolerable doses with the avoidance of damage to the skin, in the technique here described assumes a new complexion. It is the recovery period of connective-tissue fibres, fibroblasts, &c., that should be given prime consideration in the distribution of the dose of X rays.

The length of treatment time and the changeover from one chess-board series to another were influenced by data on the recovery period of fibroblasts irradiated in vitro (Lasnitzki 1943, Spear 1946) and the spacing of treatments by the Stockholm method of radium treatment in gynæcological cancer.

The effective doses were considerably smaller than those customarily used in the treatment of epitheliomas. This was the object of the method.

The histological reports on the biopsy material (Dr. P. C. Koller, of the Chester Beatty Research Institute) show that the sieve method enables one to analyse the reactions of the various tissue elements separately and to assess their importance in the radiotherapy of tumours. A fibrous differentiation of the connective-tissue cells is induced by radiation which, if it takes place before 2000–2500 r is delivered to the tumour and tumour bed, can hinder the full development of an inflammatory response necessary for the destruction of tumour and for *its supersession by granulation tissue.* The investigation clearly shows also that not only does "stroma" reaction facilitate the destruction of tumours but also that on this reaction rests the success or failure of irradiation.

The alternating chess-board method is being applied, when technically possible, in advanced and difficult cases of epithelioma, and it is not suggested that it should take the place of other more expeditious techniques. It seems to be, however, an approach by which the indirect radiation effect and the stromal effect are greatly enhanced; it might also perhaps provide a new approach to the treatment of radioresistant connective-tissue tumours.

SUMMARY

A new method of treatment of accessible tumours which is a complete departure from all the existing methods in use in both fundamentals and technical details is described.

The principle of the method is that, with a lead chess-board sieve, portions of the tumour 1 cm. square are exposed to radiation while other portions of similar area are protected so that important structures remain undamaged and can contribute to repair. *After a suitable* period of treatment another chess-board sieve, in which the order of opaque and transparent areas is reversed, is used, and the previously untreated areas are exposed while the already treated areas are protected and their recovery not hindered.

Three cases treated with the sieve method are described.

The treatment is individualised (not standardised) and controlled by histological study of biopsy material taken at various intervals of time from adjoining areas, and the dose of radiation required for the disappearance of the tumour, which is ve [illegible] those used i methods in which [illegible] both malig and normal tissue alike. The risk of necrosis is lesse to a great extent, and the indirect effect of radiatio utilised. The reactions are mild, and healing t place during treatment.

The biological implications are emphasised, and main criteria regarding the fractionation are discusse

I wish to thank Prof. Sidney Russ, D.SC., for having me on the "sieve" trail some ten years ago, when I working under his direction at the Barnato-Joel Laborato Middlesex Hospital; Prof. W. V. Mayneord, D.SC., arranging for the direct dose-rate readings to be underta in Northampton by Miss N. L. Gage, of the physics dep ment, Royal Cancer Hospital (Free); Mr. E. J. Par research technician in this department, for contrib materially to the work and for the photographs; and their willing help, the staff of the department. The w was made possible by a grant for expenses from the Bri Empire Cancer Campaign.

HÆMOPOIETIC ACTIVITY OF WHALE-LIVER EXTRACT

JAMES INNES
M.D. Edin., F.R.C.P.E.

H. N. ROBSON
M.B. Edin., M.R.C.P.E.

From the Department of Medicine, University of Edinburgh

THERE has been much discussion recently about th potency of British commercial liver extracts, an Wilkinson (1949) has stated that the use of so-calle "pharmaceutical livers" has led to a deterioration i the quality of the extracts now being produced. Corre spondence in THE LANCET has shown that this stateme has been rebutted by some and supported by others, bu it is clear that many doctors are dissatisfied with prese day extracts. It seems likely that, before long, activ and easily standardised substances for the treatment o pernicious anæmia will be obtained on a commerci

ONGENITAL HYDRONEPHROSIS AND DRO-URETER WITH CONTRALATERAL PAIN

NOBLE HUDSON
M.B. Lond., F.R.C.S.
SURGICAL REGISTRAR, WESTMINSTER HOSPITAL
UROLOGICAL CENTRE, LONDON

T is widely recognised that pain caused by a lesion in kidney or ureter may be felt by the patient not on side of the affected organ but on the opposite side. is also common knowledge that the typical pain of al colic often passes from the loin to the groin, the ernal genitals, or the upper thigh. But it is not so erally realised that pain of ureteric origin may be erred more widely—e.g., to the anterior, lateral, and terior aspects of the thigh.

etterman[1] described a case in which obstruction the right pelvic ureter in a woman caused pain in the ht lumbar region, the back of the right thigh, and the ht heel. That the pain was referred from the ureter s proved by catheterising and distending the right ter, which manœuvre reproduced the pain.

Ockerblad and Carlson,[2] using an electric stimulus, pped out the distribution of pain referred from the al pelvis and ureter and confirmed that pain from ureter may be referred as far as the heel or toes on same side.

Consideration of the segmental nerve-supply of the eter allows us to comprehend even these unusual dis-butions of pain referred from it. It is not so easy, wever, to understand why reno-ureteric pain should metimes be referred to the opposite side of the body. deed some workers deny that the phenomenon occurs. The following case may be of interest because of certain usual features.

CASE-RECORD

A well-nourished intelligent boy, aged 16, was first seen by us in the outpatient department on March 9, 1948. He complained of an ache in the left loin, passing at times round to the left groin.

At the age of 3 years he had been investigated at another hospital for hæmaturia, and acute nephritis had been diagnosed. He had had no pain until he was 14 years old, when he had begun to note intermittent aching in both loins. The attacks of pain had been variable, lasting sometimes an hour and sometimes a day.

In August, 1947, the patient had been in another hospital with a septic foot. While there he had had an attack of hæmaturia which had lasted three days. It is not known whether he was then being treated with sulphonamides or not.

On Feb. 29, 1948, nine days before we first saw him, he had had hæmaturia which had lasted a day. There was no blood in the urine when it was examined by us.

An excretion pyelogram on March 9, 1948, showed no renal calculi. The left pelvis and ureter appeared normal. There was well-marked right-sided hydronephrosis and hydro-ureter. Both kidneys secreted and concentrated the dye well at five minutes and during the following thirty minutes.

The patient was placed on the waiting-list for admission, but on March 22, 1948, he was admitted as an emergency with severe pain. He said that on March 10, 1948, in addition to the pain in his left loin he had begun to get severe pains "in the left hip-joint" which would last ten minutes and had "paralysed" his left lower limb. These attacks of pain had been associated with nausea and occasional shivering.

On examination the patient was in obvious pain. His left hip was held slightly flexed, and any attempt at active movement—e.g., turning over in bed—increased the pain. He felt "a grating in the joint." Gentle passive movement caused no pain until the limits of the normal range were approached. His temperature was normal. Radiography of the hip-joints showed no abnormality. Examination of a mid-stream specimen of urine showed no pus cells and no organisms. There was slight tenderness on pressure in the right loin. Pressure in the left loin caused the patient to exclaim with pain. The pain he felt, however, was not in the loin but a sharp increase of pain in the left hip. This strange physical sign was elicited each day until his operation on March 30, 1948.

Operation.—Under general anæsthesia the lower right ureter was explored. It was found to be dilated up to a point about 1 inch from the bladder, this lowest inch being apparently of normal size. A right side-to-side uretero-cystostomy was done by Mr. Terence Millin. On regaining consciousness after the anæsthetic the patient said that the pain in the left hip had gone. Since the operation the pain has not recurred and the patient has been free from symptoms.

DISCUSSION

The cause of the obstruction was apparently an achalasia of the lower end of the right ureter. Until the age of 14 there had been no pain. Pain was latterly referred to the left side of the body and pressure in the left loin caused pain in the left hip. Pressure in the right loin did not. The pain was promptly and completely relieved by anastomosing the right ureter above the obstruction to the bladder.

Hæmaturia was never observed by us. If hæmaturia indeed occurred on the three occasions mentioned by the patient it may possibly have been caused by urinary infection. Examination of the urine on March 23, 1948, showed no pus cells or organisms. The pain on admission was therefore not due to urinary infection.

Since the function of the right kidney was good, it cannot be suggested that the left-sided pain was due to tension consequent on a compensatory overworking of the left kidney. The clinical findings and the immediate relief of the symptoms by operation make it certain that the pains in the left loin and left hip were referred from the right ureter.

My thanks are due to Mr. Terence Millin for permission to publish the notes on this case and for much help and encouragement.

(2) Allergic manifestations at these sites and elsewhere are accompanied by an eosinophilia, either local, general, or both (Tuft 1938, Urbach and Gottlieb 1946).

(3) Eosinophilia and the allergic reaction produced experimentally develop after the same interval of time.

(4) Allergic patients' blood releases histamine, in vitro, in the presence of specific antibody and antigen (Katz and Cohen 1941); hence, in the light of Codo's (1937, 1939) experiments, eosinophils release their histamine.

The importance of the eosinophil is indicated by the work of Mayer and Moncorps (1926), who found that injection of methyl-alcoholic extracts of spleen produced a definite hypo-eosinophilia, which was of therapeutic value in various skin diseases and in the prevention of anaphylactic reactions.

MECHANISM OF EOSINOPHILIA

If, then, as the experiments quoted above seem to indicate, foreign protein per se is not the specific factor causing eosinophilia, what is? Some factor or substance in the allergic process other than the antigen must be the chemotactic and stimulating agent.

I suggest that antibody constitutes such an agent—i.e., antibody attracts eosinophils chemotactically, and increased circulating antibody stimulates production of eosinophils. Bunting (1932) stated that the products of destruction of lymphocytes are specifically chemotactic for eosinophils, and Ehrich and Harris (1942), Kass (1945), and other workers claimed to have shown that lymphocytes contain antibodies.

Eosinophilia is evoked only by repeated injections of a specific protein. This points to the operation of a specific factor. It is difficult to attribute this specificity to the bone-marrow or to the individual eosinophil cells, especially since eosinophilia will occur with any foreign protein, provided repeated injections of the same protein are given. But we do know that antibodies and antibody-producing tissue possess the property of specificity. A second injection, after the latent period, stimulates an increased production of antibodies and also produces a well-marked eosinophilia.

Ling (1925) and Biggart (1932) reported a slight blood eosinophilia after a single injection of foreign protein, but this rise was not comparable with that obtained after a second injection. The work done on primary and secondary responses of antibody-producing tissue indicates that non-particulate antigens (foreign-protein solutions) will often produce little or no antibody response to a first injection but produce a well-marked response to a second injection. Though a first injection of particulate antigens (bacterial suspensions) produces more antibodies, the difference between primary and secondary responses is just as well marked (Topley and Wilson 1946). It is noteworthy that antibacterial immunisation is always followed by an eosinophilia (Hajós 1928, Whitby and Britton 1946).

Again, non-specific stimulation of specific antibodies seems to occur ("anamnestic reaction") but is not comparable with specific stimulation. The same is true of eosinophilia (Biggart 1932).

The constantly found postinfective or postfebrile eosinophilia could be correlated with the steady rise to its maximum of the antibody titre during the recovery and convalescent stages. The antibody titre of patients with intestinal parasites is usually very high (Urbach and Gottlieb 1946), and such patients usually show a well-marked eosinophilia.

It has been shown by cutaneous tests (Hill 1942) that infants produce antibodies after the ingestion of a new protein. The same has been demonstrated in guineapigs (Hartley 1942). The antibody titre gradually diminishes in the guineapig after protracted administration, and the same process is shown in the infant by the disappearance of the positive cutaneous test. Berger (1916) found that, when a new protein is into an infant's diet, the number of eosinophils blood is increased 9–12 days after ingestion and gradually to normal or nearly so.

The eosinophil concentration found in weal fluid, marked in allergic than in non-allergic people (K Pearson 1934), may be due to selective chemotaxis eosinophils exerted by the serum-antibody in the fluid. Allergic patients will have more antibodies their blood.

The eosinophil response in bacterial disease is by the neutrophilia which is usually present, for been shown that in almost all conditions neutrophilia the eosinophils are diminished or (Simon's septic factor). This predominance of phils in septic conditions is well illustrated by observation that, when a hydatid cyst becomes neutrophilia takes the place of eosinophilia. Eosinoph is found in many syphilitics (Whitby and Britton 19 and is fairly common in pulmonary tuberculosis 1940, Whitby and Britton 1946) and more so in tub culosis of lymph-nodes (Wintrobe 1946).

When an artificial pneumothorax is induced in p monary tuberculosis it is followed by an eosinoph rich pleural effusion, and within five hours there is increased blood eosinophilia. This is characteristic tuberculosis and not due simply to the pneumothor (Piney 1939). If the eosinophilia does not devel the outlook is usually bad, and the more intense eosinophilia the better the prognosis (Ponticaccia 192 This clinical observation can be explained by equati eosinophilia with antibody-production.

The eosinophilia found in early Hodgkin's d more constant in the tissues than in the blood, may b explained by the disintegration of the lymphocytes i the glands, with the release of their contained antibodies

In an attempt to show that eosinophil chemotaxi would occur to antibody alone, I injected a norma healthy medical student subcutaneously with huma immune globulin (Lederle) in one arm and the foreign protein solution in the other. Biopsies of the site eighteen hours later showed a slight tissue eosinophili at the site of injection of human antibodies but non at the site of injection of foreign protein. The limitation of this single experiment are obvious, but the result i suggestive.

FUNCTION OF EOSINOPHIL LEUCOCYTE

It is possible to combine the ideas so far considered to provide a concept of at least part of the function that the eosinophil may perform in the human body.

Let us visualise the possible mechanism. The body has been sensitised, and the next contact with the antigen produces antibodies. These antibodies become distributed in blood and tissue fluids, and (hypothetically) eosinophils become approximated to antibody by chemotaxis, and their production stimulated. Antigen-antibody reactions, with breakdown of eosinophils, will release their histamine at the site of antigen invasion. Fluid from the blood exudes into the tissues, bringing more antibodies and therefore more eosinophils. This process will continue, and the capillaries will be rendered permeable to antibodies by histamine, until all the antigen has been neutralised.

This mechanism, I suggest, is a physiological defence mechanism for neutralising harmful antigens in the body tissues. If the reaction occurs in the blood-stream, histamine is quickly destroyed in the blood (Topley and Wilson 1946) and no symptoms may result, though there may be œdema and albuminuria (acute nephritis). Such cases would show hypo-eosinophilia, since theoretically eosinophils are broken down.

That clinical allergic manifestations may result from this mechanism is obvious, but certain conditions of

or Coughs following "Colds," etc.

'BENYLIN'

Expectorant

The ability of 'Benadryl' to relieve the cough and other distressing symptoms associated with the "common cold" represents still another clinical application of this remarkably versatile drug. The value of 'Benadryl' in controlling these symptoms is connected with its antispasmodic and broncho-dilator properties.

In 'Benylin' Expectorant, 'Benadryl' is combined with proved expectorants in a raspberry-flavoured syrup, which is readily acceptable to both children and adults.
'Benylin' Expectorant not only relieves coughs, but is also effective in alleviating nasal stuffiness, sneezing, lachrymation and bronchial congestion.

Each fluid ounce contains:

'Benadryl'	80 mgm.
Ammonium chloride	12 grs.
Sodium citrate	5 grs.
Chloroform	1½ min.
Menthol	1/10 gr.

Dosage:—Adults: 1–2 *teaspoonfuls. Children:* ½–1 *teaspoonful.*
In 4, 16 *and* 18 *fl. oz. bottles.*

Reviews of Books

Anévrysmes artériels et fistules artério-veineuses

René Leriche, professor at the Collége de France. Paris: Masson. 1949. Pp. 314. Fr. 900.

One of the conditions governing the office of professor of surgery at the Collége de France is that he must publish the course of lectures which he delivers annually. The present incumbent being Professor Leriche, his colleagues can anticipate with pleasure the monographs in which he regularly assembles his views on diverse subjects, written in the style which is his own and with the physiological outlook which has always been the feature of his major contributions to surgical literature.

This volume contains, with some additions, the lectures delivered in 1945 and 1946. As is usual in French monographs, the themes are built upon copious case-notes. Leriche's views on the operative treatment of arteriovenous aneurysms differ from those ultimately adopted by British and American surgeons. In this country and America, the operation of quadruple ligature and excision became almost the standard procedure; but Leriche holds strongly that every effort should be made to restore the continuity of the artery involved, and if possible to restore continuity of the vein—the latter a step which has been advocated by Paterson Ross. To this end he describes a number of ingenious procedures, which appear to have had immediate success; and he advocates a preliminary sympathectomy.

In the section on arterial aneurysms he insists on preliminary arteriography. He advises preliminary interruption of the sympathetic chain as a valuable immediate safeguard against nutritional changes, but prefers repeated blocking with procaine except when the aneurysm is at a bifurcation, when he regards operative sympathetcomy as essential. His preference is for operative methods which restore arterial continuity, and his case-reports contain examples of all the varied procedures available. British surgeons would endorse Leriche's general recommendations, with the possible exception of routine arteriography. They include a bloodless field, incisions so designed as where possible to leave a covering of muscle over the repair, and the routine use of heparin after reparative operations.

But the value of the work is twofold. Not only is there a wealth of experience clearly presented, with its difficulties solved: there are also—as one would expect—many arresting indications of doubt as to the inviolability of orthodox pathological explanations of phenomena about which so much has been written that one might have thought the field barren. But that is Leriche: and so to appreciate it properly the monograph must be read in full.

The Driving Forces of Human Nature

And their adjustment. Dom Thomas Verner Moore, ph.d., m.d., monk of the Order of St. Benedict; professor of psychology and psychiatry, Catholic University of America, Washington, D.C. London: Heinemann Medical Books. 1948. Pp. 456. 35*s*.

This erudite "introduction" to the psychology and psychopathology of emotional behaviour and volitional control might be more aptly described as a conducted tour. The author, an exponent of Roman Catholic philosophy, ranges over academic and clinical psychology and psychiatry, and achieves the rare feat of presenting a classification not based merely on symptoms. He is lucid, readable, and thorough in the things he covers, but there are notable omissions, and he does not inquire deeply into origins. A reader who knows the main tenets of Roman Catholicism will have no surprise in store. He will expect Professor Moore to dismiss psycho-analysis by friendly intellectual argument, which he duly does; and the gap this leaves is inevitably filled with an intellectualised concept of volition.

Despite a great number of detailed case-histories the book is in parts remote from clinical reality, especially in references to children—who are described as scheming little beggars from their earliest infancy. Professor Moore is interested in a phenomenon which he moral dullness, and which he links closely with intellectual defect. Not unexpectedly he minimises importance of sexuality as a driving force, and he asserts that sexual difficulties in the strict sense do exist in childhood except in a few exceptional cases mistreatment. Neurotic children, he holds, must made to learn by experience, and in a rather old-fashioned way too.

Readers in full religious accord with the author may share his preoccupation with making the maladjusted (and therefore bad) patient good. Others may feel this begs the question of causation of psychic difficulties—in other words that this conducted tour merely leads back to its starting-point in religious conviction of a particular type. Meanwhile this work which has great charm, may be recommended to the experienced reader in search of mental stimulation, but not to the beginner.

Zinc Ions in Ear, Nose, and Throat Work

A. R. Friel, m.d. Dubl., f.r.c.s.i. Bristol: John *Wright & Sons. 1948. Pp. 60. 5s. 6d.*

The scope of this specialised form of treatment as it can be applied in diseases of the upper respiratory tract is fully covered. Whether it is quite as efficacious as Dr. Friel suggests in the conditions for which he advises it is perhaps doubtful; but every practising ear, nose, and throat surgeon should be familiar with its possibilities and technique, and will become so by reading this well-written illustrated manual.

Exploration radiologique de l'appareil urinaire inférieur

(*vessie–urètre–prostate*) B. Fey; F. Stobbaerts; P. Truchot; G. Wolfromm. Paris: Masson. 1949. Pp. 291. Fr. 2500.

This French work is the most complete we have seen on radiological investigation of the lower urinary tract. There are nearly 300 plates illustrating every aspect of vesical and urethral pathology. The flocculation cystographic technique of Stobbaerts is particularly well illustrated.

Das biologische Weltbild

Vol. i: Die Stellung des Lebens in Natur und Wissenschaft. Dr. Ludwig von Bertalanffy, professor in the University of Vienna. Berne: Francke. 1949. Pp. 202. Sw. fr. 11.

Professor von Bertalanffy is already well known in this country as a theoretical biologist, although only one of his writings—*Modern Theories of Development*, translated in collaboration with Dr. J. H. Woodger—is at present available in English. The present work, the first of two volumes, is a general summary of the author's thought over the past twenty years. The central theme, to which he provides a great variety of illuminating glosses, is that organisation is the central problem of biology, a concept duly purged of the *mystique* with which so many writers have surrounded the idea of "wholeness." The organisation so conceived is a dynamic one, endowed with the property of self-regulation or active self-maintenance. Organismic biology has a conceptual equipment of its own and is not to be thought of as a subdepartment of physics. No-one qualified to judge will dispute von Bertalanffy's central ideas, which are now widely accepted, thanks in some degree to his own advocacy. In detailed argument there is more to take exception to, and some of the technical matter is not fully up to date. Nevertheless, this is a book which never fails to command respect.

Cystoscopy and Urography (3rd ed. Bristol: John Wright & Sons. 1949. Pp. 306. 63*s*.).—Mr. J. B. Macalpine's *Cystoscopy* has established itself as one of the standard urological textbooks in the English language. The new edition has been largely rewritten and greatly expanded, and now includes several chapters devoted to urographic and urological diagnosis. One has nothing but praise for this work, and every surgeon practising urology should have it on his bookshelves.

THE LANCET

LONDON: SATURDAY, OCT. 1, 1949

Midwife and/or Doctor

f the best possible maternity service is to be ded under the National Health Service, the al practitioner, the midwife, the antenatal clinic, the pathologist, as well as the hospital and the alist services, all have to play a part as members team."[1] At present the team spirit is not ally conspicuous; which, as Sir WILLIAM ATT[2] suggests, is perhaps not surprising in a e without unified control. When the National h Service Bill was in the committee stage the l College of Obstetricians and Gynæcologists cated a single controlling body; but the Act es midwifery between three authorities: the tal and consultant service comes under the nal hospital boards or the boards of governors of ing hospitals; general practitioners work in con- with the local executive council; and domiciliary ives are employed by the local authorities. It rd indeed to develop team-spirit in such a diffuse isation. Unfortunately it seems that the reverse ppening—for reasons that have divided pro- nal opinion sharply and therefore deserve to t out at some length.

en the service was originally planned the idea that a midwife should deliver all normal cases, that a general-practitioner obstetrician (G.P.O.) d provide "maternity medical services"—i.e., two antenatal and one postnatal examinations, the midwife advice when needed, and undertake abnormal confinement. For these duties the was to receive a fee of 7 guineas, whether he ded the confinement or not. There was never question of providing a doctor to undertake the nement except where there was a medical reason; nidwives and doctors agreed that the doctor on n the midwife might call for medical aid should the chance of seeing the patient in advance. ualify for the local panel of G.P.O.S, practitioners to produce evidence of special obstetric experi- ; and under this arrangement it would have impossible for a newly qualified doctor without raduate obstetric training to deliver a mother. r pressure from the profession, however, the ations of the health service were amended to every doctor to deliver patients who are on wn list, whether he has special experience in ifery or not. Thus general practitioners are of two s: (1) G.P.O.S, recognised by the local obstetric nittee as having special obstetric experience, may attend anyone in their area and who receive of 7 guineas; and (2) general practitioners not ecognised who may give exactly the same care to patients on their own lists, for a fee of 5 guineas—again whether they attend the labour or not. The local obstetric committees who appoint the G.P.O.S consist of the medical officer of health, a specialist obstetrician, and two local practitioners; but they seem to have been given no guidance on the principles they should follow in appointing G.P.O.S, with the result that in many regions they have put all or nearly all the local general practitioners on the list.

It was intended that the National Health Service should leave the pattern of midwifery in the country much as it had been, with midwives delivering most of the normal cases, and doctors taking their usual number of confinements and coming to the help of the midwives when difficulty arose. The proportion of confinements attended by doctors before the start of the service was actually very small. Up to July, 1948, more and more practitioners were refusing midwifery, which meant that difficult cases were gradually being concentrated in the hands of a small minority. In other words, an unofficial group of G.P.O.S was developing. Under the N.H.S., however, this trend has been steadily reversed, and doctors are taking over a higher proportion of deliveries. For this there are several explanations. Apart from the medical reasons which oblige a practitioner to assume responsibility, he may wish to widen his experience, or he may fear he will be taken off the G.P.O. list if he does not attend enough cases. Again, he is now adequately paid for the case, which, if he is conscientious, is bound to make him feel personally responsible. (Sometimes, probably, he has not digested the regulations which make it clear that he is not supposed to attend the confinement unless this is *necessary*.) He may well be constrained, too, by the need to keep up his general list: if he does less midwifery than his competitors he may lose patients to them. Finally the patient may ask him to be present, and he may find it hard to refuse. There are at least three reasons why a mother believes she is better off with a doctor than a midwife. She knows that any doctor can give her an analgesic, or even, if she needs it, an anæsthetic; whereas methods of analgesia available to midwives are limited. (The mother cannot, of course, be expected to know that an anæsthetic given in a normal case is not merely unnecessary but is likely to cause delay and lead to instrumental delivery.) Secondly she is accustomed to trust her doctor in sickness, and likes to have him in her confinement. The third reason is less important but must also be operating. In the past the mother who could afford it employed a doctor, the others had midwives: so here is an opportunity to override a former class distinction.

All these powerful drives are having their effect, doctors are taking on more normal cases, and midwives are finding themselves pushed into the rôle of maternity nurse. The danger is that in time this will have a disastrous effect on recruitment: the modern type of able midwife will die out, and something inferior will take her place—perhaps merely a glorified gamp.

Doctors can hardly be blamed for choosing to deliver more patients: they get no addition to their fee for doing so, and their motives, though somewhat mixed, contain a considerable proportion of altruism. Moreover they ask, reasonably enough, how they are to

Now from **1** injection of **PROLOPEN**

... high initial penicillin blood level

... prolonged penicillin activity

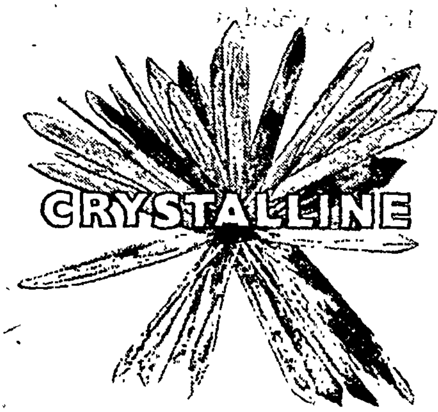
Newest addition to the new range of Glaxo penicillin preparations, PROLOPEN is a suspension of crystalline sodium penicillin G and procaine penicillin G in arachis oil with aluminium stearate. A 1 cc. injection of Prolopen provides both an early, powerful penicillin action, rising to a peak level of 1.0 to 2.0 units per cc., and a *sustained* effect lasting 24 hours or more.

This combined action of Prolopen is particularly valuable when treating conditions in which more resistant organisms are implicated (staphylococci, for instance) — organisms which cannot always be adequately countered by an oily injection of procaine penicillin alone.

GLAXO

Available in 10 cc. vials **PROLOPEN**

GLAXO PENICILLIN PRICES REDUCED as from Monday, October 3.



... now **two**

penicillin ointments

The purest form of penicillin—Crystalline Penicillin G—has been incorporated at high potency in the two new ointments introduced by Glaxo Laboratories.

Moreover, a special base has been developed which secures maximum stability of the penicillin content.

CRYSTALLINE PENICILLIN G OINTMENT *Glaxo*

Contains 2,000 units of penicillin per gram—this increased potency facilitating short-term, intensive therapy. The ointment is appropriately employed for all local infections caused by penicillin-sensitive bacteria. *In ½-oz. tubes*

CRYSTALLINE PENICILLIN G EYE OINTMENT *Glaxo*

Contains 25,000 units of penicillin per gram. Such exceptional concentration of the pure crystalline material is well tolerated and encourages penetration into the ocular tissues. *In 1 drachm tubes*

GLAXO LABORATORIES LTD., GREENFORD, MIDDLESEX. BYRon 3434 e to be a midwife. The doctor, for his part, t recognise that when all is going well there is need for him to take the delivery out of the wife's hands. After all the mother is at the heart his controversy; let both her attendants study *she* can best be served.

"Dumping" after Gastrectomy

ARTIAL gastrectomy remains the standard, and bably the best, treatment for peptic ulcers requiring gery. In a large majority of patients it achieves aplete relief. In a minority, however, it has pleasant sequels; and one of the commonest of se is the "dumping syndrome."

The symptoms are a feeling of warmth, sweating, usea, weakness, palpitation, and fullness, tightness, pain in the epigastrium. They may compel the ferer to cease work and lie down; indeed he may en faint. Though sometimes delayed for an hour two after eating, the attack usually starts towards e end of, or immediately after, the meal. It does t follow every meal, and those afflicted find that rtain foods or types of meal cause it. The pleasant sensations usually pass off in about half hour, or at once after vomiting. In most cases e syndrome appears when the patient resumes a ll diet after gastrectomy and happily it often sappears spontaneously after a few months. The atures of a typical attack were graphically described these columns two years ago by "M.D.," himself sufferer.[1]

The mechanism of such attacks has aroused much terest. After gastrectomy fluctuations of the blood- gar become wider and more sudden than normal; nd hypoglycæmia, hyperglycæmia, or increased sensi- vity to insulin have been invoked as causes of umping symptoms. But a further hypothesis—that ttacks are due to excessive distension of the jejunum y food tipped quickly out of a sphincterless gastric ump—has lately received fresh support. Irvine[2] ound no correlation between the timing of symptoms nd the level of the blood-sugar, and he attributed he trouble to mechanical distension of the small testine. In a healthy man with a normal gastro- ntestinal tract Machella[3] has now produced symp- oms akin to those of the dumping syndrome by apidly distending a balloon in the jejunum and by ntroducing into the jejunum, through a tube, hyper- onic solutions of glucose or of magnesium sulphate. urthermore, in sufferers from dumping, protein ydrolysates, administered either by mouth or directly nto the jejunum by tube, produced severe attacks. In Machella's series there was no relation between lood-sugar levels and symptoms, and intravenous njection of glucose did not produce attacks. Meals of high osmotic potential most often evoked symp- toms. In normal people Machella recovered, via a Miller-Abbott tube, large volumes of fluid from the jejunum after introducing 30 ml. of saturated magnesium-sulphate solution; and many of these normal people experienced dumping symptoms during the experiment. He thinks that jejunal distension causes dumping symptoms, and that jejunal distension is due not so much to the bulk of the meal as to hypertonic chyme attracting water to itself from the jejunal wall and thus rapidly increasing its own bulk by an osmotic process. Attacks can be prevented by taking food dry and by uncomfortably large doses of atropine, but not by vagus resection.

Machella's evidence and ideas are of great interest; but they do not fully explain those cases in which dumping arises two or three hours after food. We observed two years ago[4] that further work was needed to elucidate the riddles of the dumping syndrome. This still holds good.

Food and Fecundity

Lord Horder's address to the British Association, which we publish this week, followed a survey of World Population and World Food-supplies by Sir John Russell, F.R.S., the president. The world population, said Sir John, is now estimated at 2300 million and is believed to be increasing by 20 million a year. Some 11,000 million acres of land. or about a third of the total land area, is said to be "climatically suited" to agriculture; but for various reasons only 3000–4000 million acres is used, and 10–15% of this is devoted to industrial crops. Thus, on the average, each person in the world is fed on the produce of about $1^{1}/_{2}$ acres of land, whereas 5 acres might be available for the purpose; and there is therefore room for agricultural expansion. On the other hand, the development of new land is very costly, requiring development of transport, storage, and marketing facilities, and it is not undertaken unless profitable markets are assured. Sir John Russell accordingly concluded that the most hopeful way of increasing world food-supplies is by more intensive cultivation of the land already in use. In describing what modern equipment and modern science can do to raise the output of the soil he left most of his hearers unperturbed by the fact that everyday an additional 50,000 people sit down to the world's breakfast. An equally cheerful note is struck in a recent symposium on Freedom from Want.[5]

Nevertheless if expansion and improvement of agriculture were our only possible answer to over-population and existing malnutrition the prospect for mankind would certainly be dark. Just over 150 years ago that "clear-sighted English clergyman" Thomas Robert Malthus set out his two postulates—first, that food is necessary to the existence of man; secondly, that the passion between the sexes is necessary, and will remain nearly in its present state—and drew from them the conclusion that:

> "population, when unchecked, increases in a geometrical ratio. Subsistence increases only in an arithmetical ratio. A slight acquaintance with numbers will show the immensity of the first power in comparison of the second. . . . This implies a strong and constantly operating check on population from the difficulty of subsistence. This difficulty must fall somewhere; and must necessarily be severely felt by a large portion of mankind."

It is true, as Lord Horder says, that in Western Europe Malthus's law has not operated; and he quotes A. N. Whitehead's three reasons for this—the expansion of commerce, the development of technology, and the discovery of empty continents.

maintain their skill in midwifery if they are to attend only abnormal confinements, and those only occasionally. Increasing numbers of mothers are now being delivered in maternity homes, and the Ministry of Health propose in time to provide hospital beds for 75% of maternity patients. This fact, coupled with a falling birth-rate, will reduce the amount of domiciliary midwifery still further, and with it the doctor's opportunity of getting experience. This trend would not seriously affect their work, practitioners say, if they were given the chance of being associated with hospital maternity units; but reports from many parts of the country indicate an opposite policy on the part of hospital management committees: experienced and well-qualified men, it seems, some with higher diplomas in obstetrics who have served on their local maternity hospitals, are being told there is no future place for them in the hospital field.

But if general practitioners feel that their case is strong, it is fair that they should look again at the case as the Royal College of Obstetricians and Gynæcologists and the midwives see it; for this too is strong—perhaps on balance stronger. In the first place, if every general practitioner chooses to take up midwifery again, the average amount each will do will be very small. The birth-rate is about 21 per 1000 population and if 75% of mothers are to be delivered in hospital each doctor in the country will then have 5 domiciliary confinements a year for each 1000 on his list—a possible maximum of 20 deliveries, most of them probably of multiparæ. Even if he delivers them all (and time and multiparæ wait for no man) he will never be able, on this material, to achieve or maintain a high standard of skill in obstetrics. Furthermore, the doctor with most opportunity for midwifery will be the doctor with the big list, who should have no time to do it. Meanwhile some 10,000 domiciliary midwives in the country are faced with loss of their normal work. The standing of these midwives is very high: in England and Wales in 1947, those superintended by the Queen's Institute of District Nursing (the bulk of rural midwives) had a maternal-mortality rate for all booked cases, including those transferred to a doctor or hospital, of 0·74 per 1000 births, against 1·17 for the country as a whole. This good record must be attributed largely to the midwife's thorough training, during which she delivers at least 30 mothers (at least 10 of them in their own homes) and nurses 40 or more patients through the puerperium. It is worth comparing this experience with that of the medical student, who in his five or six years' training gets signed up for 20 cases, during the three months he spends in the obstetrics and gynæcology unit. He rarely gets much practical instruction in obstetrical analgesia, nor does he have any first-hand experience of the nursing management of the puerperium. Indeed, as Prof. HILDA LLOYD pointed out at the recent Congress of Obstetricians and Gynæcologists, the newly qualified midwife has had far better training in normal obstetrics than the newly qualified doctor; and though the latter is given good theoretical teaching on the common abnormalities it is possible for him to qualify without having seen examples of them.

There are of course many doctors in general practice who, after qualifying, gained further experience by taking a post as a resident obstetric officer; there are many splendid obstetricians among There are others—some, perhaps, equally good have frankly learned their obstetrics by pra frequently. But there are also some who have made themselves really proficient. Whereas the is closely advised and supervised throughout professional life, and is given refresher courses, young doctor going into practice has neither of th advantages. He may have a senior partner whom can call out when he is really worried, but this is a privilege any junior partner would care to nor is it always available. In these general-practitioner midwifery cannot be reproach; and in fact analysis shows that it is Sir EARDLEY HOLLAND said at the congress that had first grasped the full significance of the m mortality figures when he was set the task, duri the war, of investigating every maternal death in large county. The commonest causes of death wer shock or hæmorrhage or both; and he found that least half these deaths could have been avoided b using "ordinary standards of midwifery." T disturbing finding bore out that of the Departmen Committee on Maternal Mortality,[3] which in 193 assessed avoidable maternal deaths at nearly half th total number.

One other factor comes into play in the conduct the normal case. The midwife has more time tha the doctor to give to the mother; indeed, she ca often stay with her throughout labour—a reassurin and psychologically valuable service in itself. Sh has no way of hurrying things on; unlike the doctor who has many other calls on his time and must sometimes find the temptation overpowering to hasten normal delivery with instruments. Possibly there is le meddlesome midwifery today than there has bee at any time since the CHAMBERLEN brothers invente their humane device; but we must not pretend tha it does not exist, nor must skilful and patient doctor assume that all their colleagues share their abilit and self-discipline. For this and the other reason stated, the Royal College of Obstetricians and Gynæcologists believes that the normal case should be le to mature naturally under the care of the midwife She should of course have behind her a propert trained doctor—either a pure specialist or a selecte general practitioner who is responsible for not le than 100 cases a year and is associated with the loca maternity unit. The college fears that if we retur to the old combination of maternity nurse an family doctor without special training (which wi be the outcome of the present trend unless it checked) we shall pay a heavy price in materna lives and disability; and it is unlikely that an doctor would wish to insist on his right to practis midwifery at such a cost.

Our best hope in the present trouble is tha the doctor and midwife will work together as team; and though this would be easier if they wer under a single authority, as Sir WILLIAM GILLIAT suggests, it is not beyond the scope of human natur even as things stand. The midwife will never objec to doing a reasonable amount of maternity nursing as she has done in the past; but she cannot b expected to accept a situation in which she mus

HOSPITAL MANAGEMENT

England and Wales alone some 7000 volunteers serving on hospital boards of governors, regional ds, and management committees. In a new and il report[1] on how the hospital service is managed, P. describes it as a curious hybrid. It is a State ice, yet the managers are nearly all volunteers and of them are civil servants. Management is carried [illegible] the local-government [illegible] el at home, yet the [illegible] of Health and are responsible to an electorate. There is considerable ntralisation,' and even local autonomy, "yet the ister's writ runs throughout the service far more tively than in the case of any nationalised istry."

he Minister's intention was to create a two-tier inistration by regional boards and management mittees; but this has been extended above by the ustry's concern with matters of detail, and below by [illegible] of house committees to meet the needs [illegible] pitals.

> "It is difficult to believe," P.E.P. says, "that the resent balance is anything but temporary, and the experince of the first year would indicate that effective control s shifting towards the Ministry of Health. If it continues, his shift will deprive one of the subordinate levels, probably he regional boards, of much of its reason for existence."

is, in P.E.P.'s opinion, would be unfortunate: if onal boards and management committees are not be given autonomy, it might be better to have direct nistry administration with advisory committees at al levels.

> "It can be argued that to judge on the experience of the first year is unsound, since the Ministry was bound to keep the strings in its own hands during the formative period. Yet in view of public anxiety about the high cost of the health services it is difficult to believe that the Ministry, whatever its own wishes, will not be under constant pressure to concern itself with matters of detail."

The report examines the present method of appointent from above to boards and committees. "Taken a whole, the members of the new boards and comttees are as able and devoted a set of people as could found in command of any public service." But, dged by traditional standards, the principle of appointent by nomination from above is undemocratic, for e control which can be exercised by the people is at est very remote; the test of this system will be whether can secure better people and more balanced comittees without sacrificing that responsiveness to public eds and opinion which is, or should be, the mark of the lected representative. P.E.P. holds that the right to hare in management should not be confined to doctors nd dentists; senior members of the nursing profession, or example, have a good case to be put on the same ooting. "While there is no reason to fear that doctors nd dentists as individuals will abuse their privileged position, the possibility of the growth of medical 'syndicalism' cannot be entirely ignored." Doctors, dentists, and most others who earn their living can ill spare the time demanded of them by committee work. The burden of this might be lightened either by drawing on a wider circle of people (and in this connexion cooption to house committees should be encouraged, for these are valuable training grounds for management committees), or by reducing the amount of work which management committees themselves have to do; some of the committees' detailed work could perhaps be delegated to officers. "The tendency for the secretary to concentrate on the office side of his work, in the absorption of a mass of information, guidance, and directives from the Minister of Health and regional boards, and in the organisation of the business of his committees, all lead him away from the more solid task of knowing his hospital or hospitals and his more appropriate function of business manager and coordinating officer."

On the fundamental question of finance, the report urges that regional boards should be given block grants for both capital and maintenance expenditure over a period of, say, five years. Regional boards would then have to be granted some additional control over the activities of management committees; but this need not interfere seriously with the autonomy of these bodies.

> "Such a method of financing would relieve the Ministry of Health of the need to concern itself with matters of detail. . . . Clearly, this could not happen until the Minister was relieved of the need to be answerable to Parliament except on broad questions of policy. At the same time, the Minister would have to take a more liberal view of the degree of uniformity among hospitals throughout the country which it is desirable to achieve."

Looking to the future, the report suggests that as the service passes from the exciting formative stage to that of routine administration, the statutory administrative bodies may conceivably develop an authoritarian attitude of mind and become remote from the public whom they exist to serve. Eventually, the answer may be found in the development of regional government, of which the hospital service would be a natural part. A regional authority based on elective principles would almost certainly be empowered to raise its own funds, or a proportion of them, and this would ensure the responsibility to the public which now is only indirectly provided through the Parliamentary franchise.

RADIOTHERAPY IN LEUKÆMIA

THE incidence of leukæmia seems to be increasing. The increase apparent in mortality returns may well be deceptive, for standards of diagnosis have greatly changed and are still changing; but an upward trend has also been noted by physicians and pathologists in charge of hæmatological clinics. Despite this fact leukæmia has not yet attracted much attention from those who finance research, and even in the U.S.A. the funds for this purpose are said to be almost negligible.[1] Though the newer means of treatment—nitrogen mustards and urethane for chronic leukæmias and folic-acid antagonists for acute leukæmias—have been much in the news during the past three years, in this country most patients with chronic leukæmia are still treated with X rays.

Radiotherapy for chronic leukæmia is nearly fifty years old; William Pusey, of Chicago, treated the first case in 1902, and until recent times this method has had no serious rival. For almost as long it has been recognised that radiotherapy is quite useless in all acute leukæmias; and from the first it seemed doubtful whether the treatment actually prolonged life. In 1924 Minot and Isaacs[2] compared 50 cases of chronic lymphatic leukæmia in which radiotherapy had been used with 30 similar but untreated cases; they concluded that the mean survival-time was the same in the two groups. This conclusion—that radiotherapy does not prolong the average length of life—has been confirmed by other workers; but it must be remembered that statistics of this sort cover up the fact that a substantial minority survive longer than the average of three years, and survive in relative comfort because they are treated. As to the

VOGT,[6] in a book that one might call "Malthus Up to Date," admits that industrialisation has made it possible, during a hundred years, for the most powerful section of the human race to live as though it were independent of the earth, but points out that industrialisation in Western Europe has been so successful only because it could draw on the food and other raw materials of the new world. He pours cold water on the idea that "industrialisation" on a wider scale will raise the living standards of the whole world: in very special circumstances (which have now largely changed) Western Europe was able to exchange manufactured goods for food; but from whom could the masses of Eastern Asia buy food in exchange for the goods they might manufacture? Only from their own agricultural population. And at present, in VOGT's opinion, it is not even certain that agricultural production will not actually decrease in many areas.

> "The Yellow River transports an annual load of 2500 million tons of soil. There are other rapidly eroding regions and great muddy rivers in China, but the gutted North-West and the Yellow River are the outstanding and eternal symbols of the mortality of civilisation. . . . The Orange Free State, which descriptions of less than a century ago paint as a luxuriant prairie, is today suffering from increasing desiccation. Every year it is ravaged by sandstorms, especially in the western districts. The same situation obtains in the western Transvaal, where the dry steppes adjacent to the predesert areas of the Kalahari are an easy victim of wind erosion, once their plant cover has degenerated."

In the U.S.A. "much has been accomplished in controlling erosion and conserving soil, but in the thirteen years in which the Soil Conservation Service has existed only about 10% of the job of applying conservation measures has been accomplished. This is scarcely enough progress to justify a sense of security. And the Eightieth Congress cut the appropriations of the service! . . . We extract oil, and iron ore, and fine timber, and canvasbacks, and call it *production*. By a distortion of the Prometheus myth, we gobble our own liver and congratulate ourselves on a good meal." Town-dwellers, most of the electorate, "tend not to think beyond the butcher-shop, the can of spinach, and the milk bottle. They have little realisation of their dependence on the soil, grasslands, forests, wildlife, and underground waters."

Sir RICHARD LIVINGSTONE defines a technician as "a man who understands everything about his job except its ultimate purpose and its place in the order of the universe." To some extent most people connected with medical science have in this sense been technicians. Following HIPPOCRATES their great aim has been to save life and they have given little thought to the consequences. It is only during the last hundred years that their efforts have had much effect, and the results are becoming evident. In many parts of the world populations have been helped to increase beyond their food-supply, and the process continues. VOGT writes bluntly:

> "while the United States, through its agricultural technicians and an educational mission, is taking all too inadequate steps to help El Salvador better its condition, it is also coöperating in a health campaign designed to reduce the death-rate even further. Nothing is being done to reduce the birth-rate. As in India and Puerto Rico, this is brutally misguided well-doing. . . . One of the greatest national of Chile, perhaps the greatest asset, is its high rate. This is a shocking statement. if one does not believe there is a virtue in ha people live more miserably destroying their with increasing rapidity, the conclusion is inescapable.

But fortunately, if it is now within our power reduce death-rates it is also within our power limit birth-rates. *Lord HORDER rightly says* that fourth reason why MALTHUS's law does not in Western Europe is the growth of birth-co and it is here that VOGT too sees a way of salvation.

> "The United States," he says, "should lead in available to all peoples of the world the most m information on contraception, and the services of health and educational experts in organising control campaigns. So far as possible, these parallel, if not surpass, the older health programs of the World Health Organisation. Where finds overpopulation, its conservation and production programs should include contraception programs. It should not ship food to keep alive ten million Indians and Chinese this year, so that fifty million may die five years hence. . . . The human race is caught in a situation as concrete as a pair of shoes two sizes too small. We must understand that and stop blaming economic systems, the weather, bad luck, or callous saints. This is the beginning of wisdom, and the first step on the long road back. The second step is dual—the control of populations and the restoration of resources. Unless we take these steps and begin to swing into them soon—unless, in short, man readjusts his way of living, in its fullest sense, to the imperatives imposed by the limited resources of his environment—we may as well give up all hope of continuing civilised life. Like Gadarene swine, we shall rush down a war-torn slope to a barbarian existence in the blackened rubble."

The problem is to find some *means* of creating a judicious balance between population and resources, for so long as *overpopulation* continues to exert an intolerable pressure on food no political system will be stable. If a reasonable balance can be achieved, political systems will become less important; but we must understand that civilisation flourishes only in prosperity, and that, so long as there is a hard struggle for the means of survival, the liberty of thought and person which we in the West so greatly value will be continually threatened. Sir JOHN RUSSELL's figures are reassuring in so far as they show that the amount of food produced for each person in the world could be considerably raised by scientific farming; and Lord HORDER is no doubt right in implying that a rise in the standard of living of backward countries would itself have a contraceptive effect. But it is far from obvious that improvements *in agriculture are going to be made* where they are most needed, or that food surpluses are going to be universally distributed, or that governments and peoples are capable of taking Lord HORDER's "global view," without which *low* standards of living are unlikely to be improved. VOGT's neo-Malthusianism may be unduly alarmist; but we are all too slow to recognise that food and fecundity are basic issues, far more vital than those that *generally interest* statesmen.

THE INDEX and title-page to Vol. I, 1949, which was completed with THE LANCET of June 25, is published with our present issue. A copy will be sent gratis to subscribers on receipt of a postcard addressed to the Manager of THE LANCET, 7, Adam Street, Adelphi, W.C.2. Subscribers who have not already indicated their desire to receive indexes regularly as published should do so now.

FOOD AND POPULATION *

LORD HORDER
G.C.V.O., M.D. Lond., F.R.C.P.
IRMAN OF ADVISORY COMMITTEE ON NUTRITION, F.A.O.;
PRESIDENT OF THE FAMILY PLANNING ASSOCIATION

T is six years since Hot Springs saw one of those akenings of conscience, accompanied by a stirring of imagination, which from time to time affect not y individuals but nations, and which, again in nations in individuals, tend so soon to revert to lethargy both the spirit and of the mind. At the United Nations nference on Food and Agriculture, held in May–June, 43, enthusiasm ran high, defeatism was not recognised, d the best brains in the world concentrated upon greatest of all world problems—except perhaps avoidance of war—how to feed the human e.

The spirit of optimism which animated the conference shown in the speech with which President Roosevelt sed the final session :

> “You have examined the needs of all countries for food and other agricultural products, both as they will exist in the short-run period of recovery from the devastation of war. and as they will exist over the longer run, when our efforts can be fully devoted to expanding the production of food so that it will be adequate for health the world over. You have surveyed with courage and with realism the magnitude of these problems and have reached unanimous agreement that they can, and must—and will—be solved.”

The conference offered an excellent rallying-point for perts engaged in studying the new knowledge relative nutrition. Largely as the result of a pooling of the searches of these experts the conference ventured to m up the nutritional position under the following ur headings :

1. The kind of diet which man requires for health has been established.
2. Investigations in many parts of the world have shown that the diets consumed by the greater part of mankind are nutritionally unsatisfactory.
3. Diets which do not conform with the principles of satisfactory nutrition lead to impaired physical development, ill health, and untimely death.
4. Through diet a new level of health can be attained, enabling mankind to develop inherited capacities to the fullest extent.

Two years later the Food and Agriculture Organisation F.A.O.), the first of the international organisations nder United Nations, was set up. We were asked to dvise on certain nutritional targets, taking due account f regional differences in consumption habits and ossibilities of production.

THE FOOD

It was the job of F.A.O. to find out how much food was necessary to provide the world with the requirements e laid down. The answer ran into figures which the journalist is wont to call “astronomical.” It was found hat by the year 1960, as compared with pre-war supplies, here would be a need of 60 million more tons of cereals, 0 million more tons of meat, 250 million more tons of vegetables and fruit and 35 million more gallons of milk. As Sir Herbert Broadley, Deputy Director-General of F.A.O., comments : “a vast undertaking indeed.” Yet, such is the spirit and determination of those who lead F.A.O., there was no flinching from this gigantic task. Faced with “damage by nature and wastage by man,” with “disastrous exploitations of forests, ill-conceived methods of cultivation and short cuts to wealth,” F.A.O. turned confidently to the factors by which repairs could be effected, untilled land brought into cultivation, and technology harnessed to intensive production.

And who, listening to Sir John Russell's presidential address to the British Association—with his almost embarrassing catalogue of potential aids to agricultural development—who can doubt the ability of science to serve our ends in these directions ? The now famous Point IV in President Truman's inaugural address was not a mere mirage ; it was a call to action, and action based upon the established facts of science. To deal adequately with this technological position Sir Herbert Broadley pleads for a World Food Fund, which would supply the sinews of war. Sir Herbert thinks that the feeling of responsibility is growing amongst the nations. Let us hope he is not too sanguine in this, but we do not forget that Lord Boyd-Orr's effort at securing a World Food Board failed, and failed because member nations manœuvred for position and for power.

But it is not only in the technological field that effort is required ; there is also the economic problem that must be tackled. It is not only a question of producing more food ; surpluses and slumps have to be dealt with ; the food and the hungry people must come together ; the producer must not be induced to “pull his punches” in one place whilst human beings are being underfed in another. “A world economy which does not provide agricultural and industrial producers with a fair basis for exchanging the products of their labours will frustrate the best endeavours to increase the supply of food which the world so much needs.”

What is the present position in respect of all this ? As the result of a world tour quite recently undertaken by the present Director-General of F.A.O., Mr. Norris Dodd summarises his observations as follows :

1. Methods of food production still in use in many parts of the world are extremely primitive.
2. The conditions under which the majority of agricultural producers live are “terrible.”
3. Although they are producers of food, the great portion of the farmers have themselves an inadequate diet.
4. There are great possibilities of development, whether at the level of large projects of irrigation and draining or by the less ambitious method of providing the peasants with efficient hand tools. There are also great possibilities of improving agricultural production in all countries of the East.

Despite all this leeway to make up, the Director-General is not defeatist. Speaking to the United States' farmers the other day he said :

> “I have faith that it is not hopeless ; on the contrary, with the help of modern science, backed up by common sense, hard work, and international good will, I believe mankind can do a far better job of producing and distributing food than ever before. I am not optimistic enough to think that the world of plenty is just round the corner, but I am sure it is down the road, and we shall eventually come to it if we only make the right start and keep moving.”

THE POPULATION

“Yes,” says the critic, “but what about the world population ? What about Malthus's law ?” Well, though common sense tells us that Malthus's law must be accepted, a little thought shows that it has only a limited and a local application. Like so many “laws” relating to human affairs, it is an over-simplification. The desire to reduce human affairs to “laws” often overrides itself. It is not only in “this our life” that the soul gets “a dusty answer” when “hot for certainties” ; in demography the same thing happens. Applied to China Malthus's law clearly operates, or may do so. The population of China is estimated—reliable figures are not available—at between 400 and 500 million,

---

* Read before the British Association at Newcastle-on-Tyne on Sept. 13.

application of the treatment, some have favoured limiting it to obviously affected areas like the spleen, or to masses of enlarged lymph-glands; others prefer irradiation of the whole body, or "spray" techniques. Piney,[3] however, has pointed out with justice that the results obtained with different techniques are all about the same; "the length of the remission which is brought about is no longer when one radiological technique rather than another is employed, and the development of radio-resistance is not accelerated or postponed by any particular dosage or by exposures of different areas."

The indications for treatment have been well stated by Sturgis,[4] who puts them in the following order of importance: increasing anæmia; symptoms of pressure or pain in the spleen; progressive loss of weight; a large increase in the total number of circulating white cells or of immature white cells; increasing fatigue; progressive enlargement of the spleen or lymph-nodes; and, possibly, the onset of hæmorrhages. The white-cell count, it will be noted, does not head the list. It is certainly tempting to regulate treatment by the total white-cell count alone: it is quickly estimated, and the result provides some guide to progress and shows when treatment should be stopped. In chronic myeloid leukæmia, however, the differential count must also be watched, because, as Israëls [5] pointed out, if myeloblasts increase the prognosis is bad no matter how far the total count is reduced towards normal. Moreover, in chronic lymphatic leukæmia the patient may well have a high total white-cell count, but if he has no anæmia and the general condition is good it may be years before treatment need start. In the first issue of the new and attractive *Journal of the Faculty of Radiologists* [6] R. Bodley Scott reminds us that the clinical course of chronic lymphatic leukæmia tends to differ from that of chronic myeloid leukæmia; for the clinical and hæmatological remissions common in the myeloid form are unusual in the lymphatic. Here, for months or years, the patient suffers no more than the inconvenience of enlarged lymph-nodes; X-ray treatment may be needed to reduce the size of these tumours, but no attempt should be made to keep the total white-cell count low. Then, quite quickly, deterioration sets in, with asthenia, emaciation, and increasing anæmia, and despite treatment the patient dies in a few weeks or months; in this brief stage control of anæmia and infection is more important than control of the leucocyte-count.

It has yet to be shown that nitrogen mustard treatment will prolong life, on the average, any more than radiotherapy will; but its use is often more convenient and relieves the demand for use of X-ray apparatus. Both forms of treatment act by causing cell destruction or inhibition of cell mitosis, and the criteria for their control are essentially similar.

PUBLICITY FOR DISCIPLINARY PROCEEDINGS

THE Minister of Health has been considering the question of publicity for disciplinary proceedings taken against doctors, dentists, or pharmacists before their respective service committees. In an advisory letter to executive councils he says that, whatever method of publicity is adopted, "at no stage should mention be made of the names of the parties to the proceedings or of other particulars which might lead to their identification." The actual proceedings before the service committees should always be private, and nothing should be said about their reports before they have been considered by the executive council. The press should not be admitted while the executive council is considering report of a service committee, but can be told of council's decision, and may, if the council thinks fi given a summary of the case as reported by the ser committee and of its findings. When in due course Minister has given his decision on any case, it w again be open to the council to give further publ and in the Minister's view this would be proper in se cases. This would be no departure from establ custom; for under the National Health Insurance the insurance committees were in the habit of circul (with due regard to anonymity) an account of all ciplinary proceedings and findings to all the practiti on their lists; and cases of particular interest often described in the medical press.

RELICS OF JENNER

HISTORIANS must feel warmly to the great ma becomes famous in his own lifetime: his admirers k whose letters to keep, whose spectacles, snuffbox, lancet will be reverenced by posterity, whose little j will last for centuries. Jenner, a lovable man wh jokes were in any case good, left pleasant memories many people; and many personal tokens of him surv and may now be seen in his bicentenary exhibition the Wellcome Historical Medical Museum, 28, Portm Square, London, W.1. The trustees of the muse have published an excellent catalogue of the boo portraits, manuscripts, and relics in this exhibiti which not only describes the many items shown but car notes on Jenner's life and work, on smallpox inoculati on vaccination in Britain from 1798 to 1823, and developments since. A plate at the end shows portrait medals, each giving a different version Jenner's face, alike in nothing but a look of intellig benevolence. Monteverdi's pleasing if imaginative rec struction, in bronze, of Jenner vaccinating his appears as the frontispiece.

CLAIMS AND THE CRISIS

IT is unlucky that the negotiations over the remune tion of general practitioners should have come to a h at one of the peaks of the economic crisis, when Government are more anxious than ever to avert ri in salaries and wages. A survey lately made by Ministry of Health is said to give a reassuring picture practitioners' incomes in the National Health Servi but the general medical services committee of British Medical Association is not fully satisfied wi the evidence, and a deputation met officials of the Min try on Sept. 23 to press the committee's claim for further £16½ million to be distributed among prac tioners. Though it seems improbable that such a su would be actually paid in present circumstances, t fact does not affect the validity of the claim, and trust that it will be considered strictly on its merits.

Evidently the Government mean if possible to av cutting the social services, whose value to members the public is of course greatest in times of hardship. Sept. 25 Mr. Aneurin Bevan said that he had made his mind that the National Health Service was not goi to be touched; and there was no disposition by t Government to touch it. "The Government," he add "have made up their mind to solve their proble without raiding the social services, and the health servi is sacrosanct."[1] Previously the Chancellor of t Exchequer had said that "*no economies are to be ma in expenditure on defence and the social services, a that any cuts decided on must fall on administrati expenditure.*"[2] It will be recalled, however, that earl this year the Chancellor was considering whether charg might not be made, or a special tax imposed, to co part of the expenditure on the National Health Servic

SPERM QUALITY

A. G. **OETTLÉ** (South Africa) and Mr. G. **VAN**
ELEN, D.V.SC., have developed a theory of sperm
based upon the known facts concerning develop-
and subsequent loss of the characteristics of
y and ability to fertilise and to ensure completion
ryonic development. It is hoped that a considera-
the subject in this way may help to show where
work is needed to fill in some of the many gaps
vledge.

ANOVULATORY FAILURE

G. I. M. **SWYER** described a method of treating
ulatory failure" by oral administration of stilb-
and ethisterone in cyclic courses. He reviewed
ults in 40 women in the reproductive years. In
presenting symptoms were prolonged and excessive
r uterine bleeding; in 13 the periods were scanty
requent, or, if regular, were anovular; and in
ndary amenorrhœa had been present for one year
. In the first group evidence for the re-establish-
f ovulation was found in 8 cases and there were
nancies; in the second group the results were
; but in the third group no successful results at
d be claimed.

discussion centred on the problems in diagnosing
tory failure before treatment and eliminating
eous cure—in other words the difficulty of
g results to the effect of treatment.

RE-ESTABLISHMENT OF OVULATION

ALBERT SHARMAN (Glasgow) read a paper on the
lishment of ovulation post partum and post
n. This work forms part of a wider investigation
s not yet completed. He referred to five previous
ations on the re-establishment of ovulation—all
l series of cases—with considerable discrepancies
results. His own series consists so far of 628
trial biopsies in 283 women post partum and
psies in 36 women post abortum; 17 patients have
re than 10 endometrial biopsies performed during
e months following delivery, several having been
l at weekly intervals and one patient weekly
nty-four weeks. From this material Mr. Sharman
e to give a full account of the re-establishment of
ry cycles and their relationship to lactation.

ENDOMETRIOSIS

G. **DOUGLAS MATTHEW** (Edinburgh) discussed
endometriosis in relation to sterility and showed
ditional disorders, such as fibroids, metropathia
hagica, and fixed retroversion frequently coexist.
sis may be most difficult, especially since the
of symptoms is not necessarily related to the
of the disease; laparotomy therefore is the only
diagnostic procedure. Conservative surgery is the
nt of choice; if this is rewarded by pregnancy
currence follows, more radical measures can
ently be adopted.

PERITONEAL POCKETS

. **BENDER** (Liverpool) drew attention to peritoneal
as a cause of sterility. They usually result from
peritonitis, which may or may not have caused
lamage. Although tubal patency is carefully
gated in cases of sterility, attention is seldom
the pathway between ovary and abdominal
Obstruction of this pathway, or pelvic block,
due to a pelvic pocket in relation to the abdominal
—easily demonstrated by salpingography—but it
o be due to the ovary being pocketed away from
eral peritoneal cavity, and then the pelvic block can
nosed only at laparotomy or possibly by culdoscopy.

PREVENTION OF ABORTION

LINTON SNAITH (Newcastle-on-Tyne) has been
œstrogens in the treatment of threatened and
habitual abortion for the last two years. In threatened abortion, provided it is not inevitable, an initial intramuscular injection of 10 mg. of œstradiol benzoate is followed by oral œstrogen therapy. In habitual abortion œstrogens are given by mouth, starting a few days after the first missed period. Of 31 patients in this group (in half of them stilbœstrol alone has been used) so far 25 have advanced sufficiently to be regarded as successful cases; in many of these other methods of treatment had previously failed. Among these cases there is a surprisingly high incidence of toxæmia of pregnancy. Mr. Snaith concluded that while there is no evidence that œstrogens do harm in pregnancy, they may be beneficial, especially where "blighted embryo" in the early months of pregnancy has given rise to repeated abortion.

In the discussion attention was drawn to the difficulties of defining habitual abortion and of assessing the results of treatment. It was curious how, despite the difference between their treatments, nearly all authors secured approximately 80% of successes. The random distribution of abortion sequences, as in the classical description of Malpas, had to be considered, and it seemed that only an extensive controlled trial could be expected to prove the value of any therapeutic régime.

SEMINAL STUDIES

Miss **URSULA PARSONS** (Cambridge) described the work which she and Dr. T. Mann have done on the effects of testicular hormones on the formation of seminal fructose. Very considerable variations in the seminal fructose concentration—both in the same and in different individuals—are found in man and in rabbits. In the latter, however, castration is followed by a fall in the seminal fructose almost to zero, while the administration of testosterone is followed by the rapid return of the fructose to normal levels, from which it falls again on removal of the implant. Dr. **MANN** described how the fructose content of the castrated rats' prostate and seminal vesicles are used as an indicator of androgenic activity; this method is far more sensitive than weight-change and, he suggested, should prove satisfactory for androgen assay. By this means it was possible to detect as little as 0·05 mg. of testosterone and to show that progesterone had about $^1/_{2000}$ the androgenic activity of testosterone.

Mrs. **CLARE HARVEY** (Exeter) described a relatively simple method of estimating the rate of liquefaction of blood-fibrin by seminal fluid. The time of liquefaction of a constant quantity of fibrin is related to the fibrinolysin activity in a manner expressed by $\log C = a \log T + K$ where a and K are constants, C is the fibrinolysin activity measured in arbitrary units, and T is time. A regression equation calculated for 99 points from 30 specimens of semen gave a very good fit for a further 110 points from 45 other specimens. The distribution of enzyme activity was found to be asymmetrical, most specimens having a total activity below 50 units. No correlation was found between enzyme activity, sperm motility, seminal volume, time of continence, or fructose content. The residual viscosity of semen is not closely related to enzyme activity, but citric acid, thrombin, and fibrinogen content may be at least as important as fibrinolysin activity in determining the final consistency of the seminal plasma.

FUTURE MEETINGS

At the close of the meeting it was decided that these conferences should be continued. It was also decided to form a committee, of which Dr. A. Walton and Dr. G. I. M. Swyer were elected joint secretaries, the functions of which should be: (1) to arrange for a conference next year, and (2) to plan for the formation of a society to study problems in comparative fertility.

and is probably increasing at the rate of 6 million per annum. During peace, China can feed some 400 million people on the basis of a mere subsistence level. If she desires a higher standard of living, which connotes a diet giving a better margin of nutrition and therefore of health, she must do one, or both, of two things; either she must grow, or import, more, and more varied, food, or else she must limit her population increase. But China may do all of these things and so demonstrate that, even in her case, Malthus's law may not be operative. The time factor is clearly imperative; will increased production, with or without importation, catch up on increased population? Or will it not?

In Western Europe, on the other hand, Malthus's law does not operate at all, nor has it for a thousand years—and for three reasons, as pointed out by Professor Whitehead: the expansion of commerce, the development of technology, and the discovery of empty continents. Although China cannot find more empty continents, industrial expansion and technological development have scarcely begun with her.

But there is a fourth factor which has operated in making Malthus's law of no sociological significance in Europe during recent years, and to which Whitehead makes no reference. This is the practice of some form or other of birth-control.

It has been alleged that so called "primitive" populations would have nothing to do with family limitation in any form, that large families are a tenet in their religion or tradition. But the view of those who have actually lived amongst such people tells a different story: the womenfolk frequently ask for information on the spacing of their children. It would seem an almost universal desire of women to seek help against the bondage of too frequent pregnancies. The working out of the principle of contraception in face of the traditional cultures and social institutions in China and elsewhere will probably fall to the lot of the women themselves. Hence the value of antenatal, neonatal, and other clinics where women may receive instruction.

Two further considerations are pertinent in this connexion. The first is that governments and other controlling authorities should not only allow, but should encourage, contraceptive instruction. Thanks largely to the work of the Family Planning Association this position has been, in a fair measure, secured in this country. Public opinion, as always, has dictated policy.

The second consideration is that more research should be undertaken in pursuit of simple, but effective, techniques. I think it was that courageous and persistent pioneer, Margaret Sanger, who commented on the fact that whereas we had succeeded in splitting the atom, with certain dire consequences to human life, we had not yet found a simple and harmless contraceptive. But we shall, and perhaps by a method quite different from those in present use. In scientific discovery the wind bloweth whither it listeth and we cannot foresee the direction in which any new addition to our armamentarium towards the goal of human progress will appear. Nor, I am inclined to add, to what bad, as well as to what good, purpose *man* will put it.

What really matters is that we possess the will to achieve biological control, as to which many of us are still in the stage of confused thinking.

I do not mean by these remarks that I regard intensive propaganda concerning the voluntary limitation or control of births as the panacea for the maladjustment of food and population in the world. History shows that when the standard of living rises, by whatever means this be achieved, such propaganda from without a social group becomes less and less necessary. It may be said of any nation that if it raises its standard of living this matter, as many others, will be added unto it.

THE SPIRIT OF MAN

Sir John Russell has warned us that though can be a very efficient provider of benefits it does make a choice, or a decision, as to their use. That with the spirit of man.

But on this point, even after a second world I am an unrepentant optimist. I take it that a may quote himself without being charged with plagi At the meeting of this Association at Blackpool in l speaking of the strain of modern civilisation, I tou on this subject. I said:

> "I believe that 'man can elect the universal I have faith that the human heart *is* 'made of pene stuff.' I do not think that 'damned custom' has ' it so. That it is proof and bulwark against sense'; t at this moment a morbid Hamlet, looking on, doubtless take a different view."

Today I shall conclude my admittedly cursory re of the position by a statement which, in respect o I may call my creed:

1. We must take a global view of the problem; unles do so we cannot hope to solve it.
2. We must work, for we cannot escape the injunct "if ye do not work neither shall ye eat."
3. We must encourage ideas and we must secure com autonomy for science.
4. We can, if we will, achieve physical, chemical, biological control on the earth and thereby effe satisfactory adjustment in regard to food and popula
5. Moral control is the ultimate and overriding consic tion. Its most primitive expression is "live and live." Without this even survival cannot be assure

---

CONFERENCE ON INFERTILITY

A CONFERENCE on infertility—the sixth in an an series—was held in Edinburgh on Sept. 17 and under the auspices of the Family Planning Associatio

TESTICULAR BIOPSY

In the opening paper Mr. W. SELBY TULLOCH (E burgh) described a technique of testicular biopsy by him as an outpatient procedure. It is perfor under local anæsthesia, 10% procaine being inje into the spermatic cord and into the scrotum at the of incision; suture of the tunica albuginea prev hæmatoma formation. In none of his cases has operation involved absence from work.

In the discussion that followed attention was dr to the danger of testicular damage from the X- treatment of spondylitis ankylopoietica and to absence of evidence of inflammation in biopsies f testes which have been the site of mumps orchitis.

SEX BEHAVIOUR

Mr. ARTHUR WALTON, PH.D. (Cambridge), showed t characteristic male sex behaviour is not sex-spe since it is exhibited by the prepubertal male, it n persist after castration, and at least in some specie is normally exhibited by sexually excited females. pattern is innate and shows the phenomenon of "driv which increases in the absence of normal outlet so t a substitute outlet may be found. Experimental w on rabbits has shown that the threshold of respo and the degree of completeness of the pattern depe on two factors—the sex drive of the male and excitatory value of the sexual object. The motor patt and accompanying reflexes can become highly conditio to external stimuli, as Dr. Walton illustrated from study of the behaviour of bulls during semen collecti for artificial insemination.

In the discussion the importance of lack of sex dr as an infertility factor was exemplified by the incide of 5% for intact hymen among wives of infertile coupl ıe percentages gradually reach a maximum at just 70%. The low figure in the adult age-group is ımably due to failing memory about infantile illness to less interest taken in the history of other infectious ıse in the case of older patients.

ıe level of notifications in 1945–48, however, if inued, would imply that only about 60% would be ıed before the age of 15, a considerable fall in risk ıttack as compared with pre-war conditions. A lar series of figures for England and Wales as a le is not available; there were no national figures re 1939, when measles became generally notifiable ıe country. Stocks (1949) has calculated, however, the average notification-rates experienced in land and Wales in 1944–47 if continued would ly that only 47% of children will have a notified ck before the age of 15. The difference between national proportion of 47% and the London proıon of 60% is presumably due to the different dard of reporting outside London, with possibly a ing incidence depending on population density; the difference in London between the pre-1938 portion of 78% and the post-war proportion of 60% ot due, so far as can be judged, to any changes in standard of reporting.

efore the effect of the reduced incidence on the tage level of susceptibility can be assessed, it is ssary to ascertain whether the reduction in incidence lies equally to all age-groups. The system of reportı to Metropolitan Boroughs in pre-war epidemics, ending as it did on information drawn from school horities, health visitors, doctors, &c. did not adeıtely cover the preschool ages, and the age-distribution icated was correspondingly curtailed at very young s. With this fact in mind the relative numbers at h age in the typical epidemic of 1935–36 (London nty Council 1938) are compared with the distribution notifications in 1945–48 as follows:

e-incidence of measles (% of total no. of children aged 0–14 yr.)

	0–1 yr.	1–3 yr.	3–5 yr.	5–14 yr.	Total
ases reported to M.O.H.s of Metropolitan boroughs, Nov. 1, 1935 to Aug. 31, 1936	4	18	33	45	100
otifications 1945–48	6	29	27	38	100

No definite conclusions can be drawn from these ıres, but the impression is strong that the difference tween the two distributions arises mainly from the vitable under-reporting at ages 0–3 years in the 35–36 epidemic under the arrangements then operative. the absence of any conclusive evidence to the contrary must accept the reduction in post-war incidence as ıng fairly evenly spread over all age-groups.

Unless there has been an increase in what Stocks and ırn (1928) call latent immunity, a general fall of 20% the attack-rate would imply that in passage through h year of age an infant's risk of being attacked has llen by this fraction, and at any age the chance that he she has been attacked has fallen by about 20%.

The lessened incidence has been operating for almost e whole of the past ten years, and one may therefore sume that in the present population of children under e age of 14 the proportion attacked has fallen by 20% the pre-war level up to the age of 10 years and beyond ıat age by a smaller fraction corresponding to the ıngth of pre-war exposure. We may estimate, by pplying this assumption to the sample "history of ttack" figures above, that the *average* level of usceptibility, or proportion of what Hedrich (1933) alls "intacts," has risen from 43 to 50% at least, ınd that before a winter outbreak it has recently een about 55%, an "explosive" level by pre-war tandards.

This change needs explanation, and with it the concomitant feature which is also mysterious, the disappearance of the biennial rhythm.

BIENNIAL RHYTHM

The biennial swing in the incidence of measles observed in pre-war years was not peculiar to London but was observed in most towns in the northern hemisphere. As an example we compare the figures of reported cases in New York with those in London in 1921–48. Both sets of figures involve a degree of approximation, in that they depend on the completeness or otherwise of notification in the two systems of reporting; this factor is, however, reasonably constant from year to year. In London, where for continuity we have used cases reported from schools (the disease did not become notifiable until 1938), an additional error is introduced by the fact that over most of the period it is impossible to separate the rubella figures, which are therefore included for comparability purposes in a composite total *throughout*—we believe this error to be insignificant, but we have no precise measure. The data are represented in fig. 2 (the measles notifications in England and Wales have been added as a background). The diagram shows the following facts:

(1) In both cities there is for the most part a series of alternate heavy and light years, one year being mainly covered by an epidemic and the next being mainly interepidemic.

(2) The two towns "change step" at irregular intervals, and therefore their epidemics sometime occur simultaneously and at other times do not.

(3) Since 1940 New York has maintained the pre-1940 rhythmic pattern, except that since the heavy epidemic of 1941 (a year later than expected) incidence has been generally lighter. In London the post-1940 pattern is quite different from that of pre-war years, each year containing a greater or lesser outbreak of epidemic nature but never attaining the proportions of a pre-war peak. From fig. 2 and the more detailed curves shown in fig. 1 it is clear that it is impossible to speak of biennial epidemics in London after 1939, and that any discussion of two-year periods, as if they included major and minor phases of a biennial cycle, is straining the statistics.

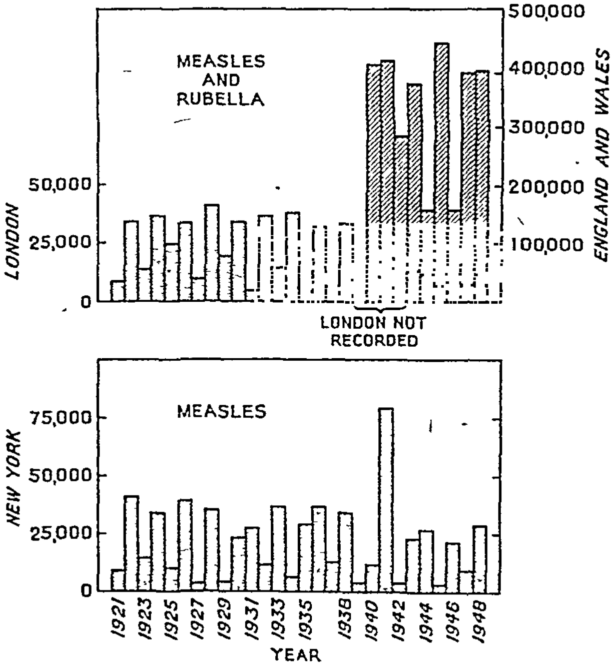

Fig. 2—Biennial rhythm of measles (shaded area, England and Wales).

Public Health

MEASLES IN LONDON

G. E. Breen
M.D. N.U.I., D.O.M.S., D.P.H.
EPIDEMIOLOGIST

B. Benjamin
B.Sc. Lond., F.I.A., F.S.S.
STATISTICIAN

PUBLIC HEALTH DEPARTMENT, LONDON COUNTY COUNCIL

ANY attempt to compare the incidence of measles in London during and after the war is made difficult by the fact that measles did not become generally notifiable in the County of London until October, 1938, and only one year of notification, and an interepidemic year at that, preceded the outbreak of war in September, 1939.

For estimating the number of cases which would have been notified if general notification had been in force (as under the existing regulations) before 1938 there are our independent sources of information:

(1) Measles was notifiable before 1938 in some London areas, and reference to these records indicates the level of incidence in London as a whole.

(2) Cases of measles coming to the notice of school authorities have always been recorded, and for the period from 1939 to date these records run concurrently with statutory notifications; by gearing notifications to school reports we can estimate the number of cases which would have been notifiable before 1939 if the notification order had been in force.

(3) Over a short period of stability in admission policy, hospital admissions also provide a guide to incidence. The details of these methods are shown in the Appendix, and the results are given below.

(4) If the pre-1939 case-mortality trend can be assessed, the recent movement of the ratio of notifications to deaths might be extrapolated and the series of ratios applied to deaths to yield the corresponding "notifiable" cases.

The results obtained by these methods of estimation are as follows:

ESTIMATES OF NOTIFIABLE CASES OF MEASLES. LONDON ADMINISTRATIVE COUNTY

—	I Local notifications (St. Pancras)	II School reports (× 2·5)	III Hospital admissions (× 8)	IV Based on case-mortality	V Final estimate 1931–38. Actual cases 1939–48
1931	12,000	7500	..	11,000	10,000
1932	80,200	83,750	..	82,200	80,000
1933	12,200	25,000	..	10,800	15,000
1934	101,800	95,250	96,300	99,300	98,000
1935	3360	6750	6200	2600	5000
1936	83,200	79,000	102,300	86,500	85,000
1937	17,860	10,450	13,800	4000	15,000
1938	65,400	79,300	74,300	53,400	64,000
1939	Measles generally notifiable				1303
1940					5447
1941					11,039
1942					19,987
1943					22,882
1944					7499
1945					23,518
1946					22,517
1947					17,486
1948					30,367

Up to the 36th week of 1949 the total cases notified numbered 28,126, and the curve has now descended.

The values of column IV are in many cases too low in non-epidemic years, presumably owing to the fact that in these years of mild prevalence the actual case-mortality is lower than the average deduced from epidemic and non-epidemic years combined. On the whole the various estimates are fairly close. The figures of the final column represent an arbitrary choice after reviewing these independent estimates. The two doubtful years are 1933 and 1938, when the figures based on school reports are much higher than other estimates. Pro since the ratio notifications to school reports was at the end of 1938, it was less than 2·5 over the w year, and the same error probably applies in l In making the final estimates for these two years sc reports were ignored.

The figures in column V have been distributed in fo weekly periods from 1936, and the four-week le are represented as ordinates of the curve shown fig. 1.

POST-WAR INCIDENCE

The important point must be made that in colum of the foregoing data the figures are intercomparable far as the standard of reporting is concerned. the calculations of incidence are based on methods

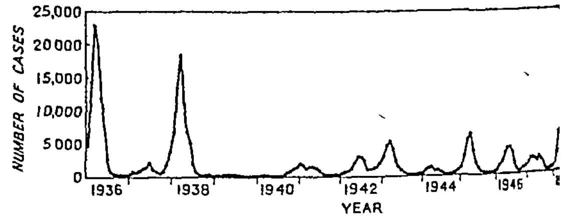

Fig. 1—Incidence of measles in London Administrative County 193 notifications in four-week periods 1939-48; "notifiable" cases 193 annual totals as estimated in text and spread over year in propor to distribution of cases reported from schools.

assumptions that yield estimates of the number of ca which would have been notified if the *same standard* notification had been in force before 1939 as subsequent

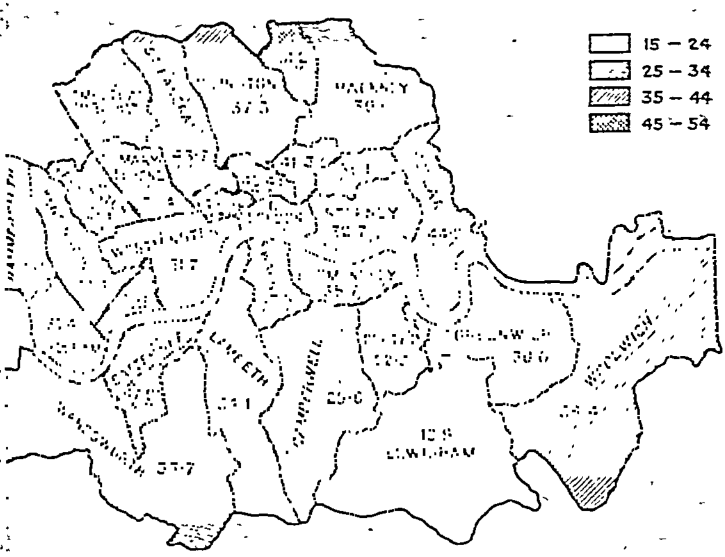
Taking an even number of years to explain the bienn rhythm in pre-war years, and excluding years wh evacuation was operating extensively, we obtain t following comparison of the average level of incidence:

Years	*Average population aged 0–14 yr.*	*Average annual no. of cases*	*Average annu cases % of average population*
1931–38	874,000	46,500	5·3
1945–48	578,145	23,472	4·1

The average incidence over the last four years is th only 80% of expectation.

The proportion of patients over the age of 15 years small; in 1945–48 it was only 2·5%, and we may ther fore assume that a "notification"-rate in the age-grou 0–14 for 1931–38 was about 5·2% annually, and tha ignoring the progressive reduction in survivors, mortality, between birth and the age of 15, about 78 (15 × 5·2) of children would have been notified having had an attack of measles before attaining t age of 15. This agrees reasonably well with the calcul tions of Stocks and Karn (1928) based on St. Pancra *leading to the suggestion that the pre-war position* London was that on the average 70% of the populati had had measles before the age of 10 years. It agre also with the past history relative to measles of a samp of patients admitted to L.C.C. infectious-disease ho pitals in 1938 for treatment for diseases *other tha measles*—i.e., as regards measles their history mig be expected to be typical of the general population.

Age	*Number in sample*	*Percentage with history of measles*
0–	587	2·7
1–	447	16·1
2–	406	27·8
3–	365	41·1
4–	268	53·7
5–	268	62·3
6–	236	70·3
7–	177	71·2
8–	137	76·6
9–	127	61·4
10–14	301	74·1
15–	1466	40·4



3—Measles attack-rates in London Administrative County 1945–47 among children up to the age of 14.

ugh a considerable percentage of susceptibles was not acked. The low incidence of the subsequent year was ributed to the immediate considerable decrease in ceptibles, who then, continuously augmented by ths, gradually increased in numbers over a period of ghly eighteen months to the figure required to initiate urther epidemic. Hamer's work was carried further Soper (1929), who introduced the conception of sonal variation in "perturbing influences." and alysed the epidemic curves likely to arise from hyposes which took account of seasonal factors as well the accession of susceptibles.

Soper's analysis went a considerable way (half-way his own estimation) towards explaining the vagaries the epidemic curve actually observed. In the discussion Soper's paper Halliday (1928) made the point that pography and rate of spread throughout an urban it must be taken into account :

> If the population was large, or if it was well-dispersed oughout space, measles in the form of outbreak had dom time to traverse the whole area before the refractory iod set in in May. the result being that annual outbreaks dominated. Such was the case for towns e Paris and Edinburgh."

is true that the population of ndon, particularly the child population, was considerably rarefied during e war years in terms of persons per it area, but such dwellings as were cupied were not less crowded than fore, and when one considers shelter e and crowding in such schools as caped damage, there can hardly ve been less intermingling. By 1946 the latest the child population under e age of 14, though lower than before e war, had reached the 500,000 level, d there was considerable housing hortage involving crowding. One would ave expected a return to the pre-war pidemic rhythm. However, the facts bout the real disposition of the population during and after the war as gards spread of infection are difficult o elucidate, and the suggestion that Halliday's theory might apply to wartime London cannot be dismissed out of hand.

Speaking generally, the mathematical development of the law of mass action was supported by pre-war experience in London and played its part in enabling hospital authorities to foresee and plan in advance to meet their commitments. This statistical approach was in turn carried considerably further by others, including McKendrick (1940), who postulated a threshold density of susceptibles above which an epidemic became extremely probable. Hedrich (1933), from his study of measles statistics in Baltimore, has shown that, apart from seasonal variations in the years 1900–31, super-cycles of fifteen years or thereabouts also occurred. In his findings in Baltimore the immunes, or "intacts" as he prefers to call them, never fall below 32% or rise above 53%. Somewhat lower figures had been advanced by Thomas (1907) for infant classes in schools :

> "Measles tends to spread when an (infants') class accumulates unprotected members to the extent of 30–40%, and when spread has begun it continues until the proportion is reduced to 15–20% protected."

Stocks and Karn (1928), as a result of a very thorough examination of the incidence of measles in the borough of St. Pancras, introduced a novel explanation not only of the periodicity, but also of the still more challenging fact that epidemics end even though many susceptibles appear to remain unaffected. This was that during an epidemic a process of temporary latent immunisation by means of subclinical attacks was set in motion in the proportion of roughly 1 clinical case to 4 or 5 temporarily immunes, this temporary immunity enduring only for about eighteen months or two years—i.e., until the next epidemic. Halliday (1928) in Glasgow put forward the same idea.

In contrast with the purely statistical approach is the theory of parasite variation associated with the names of Brownlee (1909) and others who believed that the rôle of the parasite was much more important than that of the host. In this view periodic fluctuation in the infecting power of the virus was the factor chiefly concerned. At the beginning of an epidemic the power

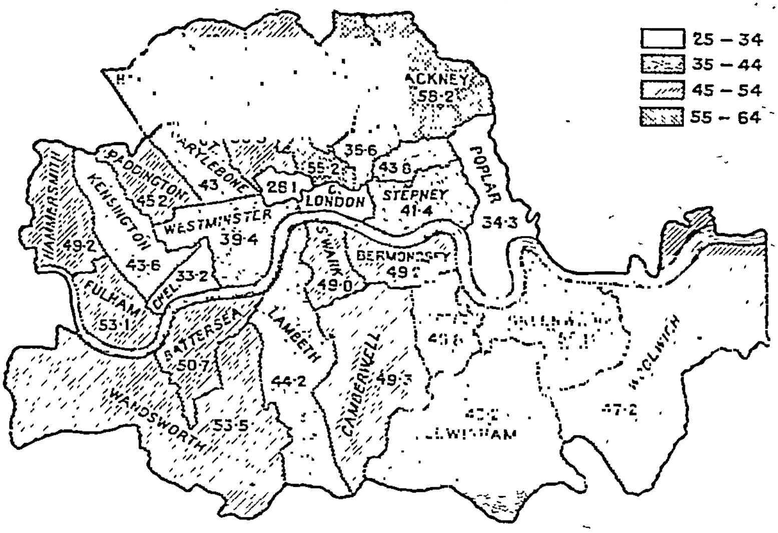


Fig. 4—Measles attack-rates in London Administrative County 1935–36 among children up to the age of 14.

(4) For England and Wales as a whole there has been some alternation between light and heavy years, but to say that measles has been epidemic four times is to overlook the fact that the figures represent the sum of a large number of experiences, and, even when the *total* figures suggest a minor phase, measles is still epidemic in some districts. This has been demonstrated by Taylor (1948), who remarks: "Consideration of the rise and fall of measles epidemics in the individual counties of England in 1946–47 disclosed a remarkably wide variation in the timing of peaks in different areas. The peaks were by no means all in the late winter and spring, the scatter being wide (although not completely random) throughout the year." One feature only was universal—i.e., low incidence in autumn. Butler (1948), by combining six years' notifications in two-year periods, and sharpening the peaks of the composite curve by expressing incidence as a percentage above or below the mean, insists that the biennial cycle has been followed, but there is a peculiar irregularity in the alleged "major phase" of 1947. It seems clear, however, that the term "biphasic curve" has in the post-war era lost much of its application. As Taylor (1948) shows, when the national figures for the two-year period are broken down into constituent areas, there may be "two annual epidemics or one large (unsplit) peak in the two-year period."

The numbers of reported cases in London, in New York, and in England and Wales were as follows:

—	London	New York	England and Wales
	(Reported from schools *)	(Reported cases)	(Notifications)
1921	8317	7738	..

*The London figures are for measles and rubella; for most of the period it is impossible to separate rubella.

SOCIAL CONDITIONS

If the incidence of measles has in fact fallen since 1938, some cause must be sought for the decline. It is natural to turn first to the examination of the possible effect of social conditions on the incidence of measles, so that changes in such conditions during and since the war may be given adequate consideration in resolving this problem of discovering a cause for the lowered incidence of measles.

The County of London is split into 28 metropolitan boroughs (ignoring the City of London, which for this purpose has too small a resident population to be of value), each with different social characteristics, and an intercomparison of these characteristics in relation to the incidence of measles should indicate the rôle of environment factors if these exist. The investigation was made over two periods: 1935–36, and 1945–47. For the earlier period school reports provided the evidence of incidence, whereas for the later period *statutory notifications* were available.*

In the pre-war period of two years, 1935–36, average annual *attack-rate* ranged from 28·1 "equi notifications" per 1000 of population under the age 14 (in Holborn) to 62·6 (in Stoke Newington). T mean rate for the county was 46·5 ± s.e. 7·8. T the incidence in certain areas tended to be consisten high or low is indicated by the statistically signific correlation (+ 0·582) between incidence in 1935 and incidence (on the same statistical basis) in 193 for the 28 London boroughs.

In the post-war period of three years, 1945–47 (th is no biennial swing to favour a two-year period) average annual notification-rate ranged from 19 1000 of population under the age of 14 (in Lewisha to 51·2 (in Stoke Newington), with an average for county of 38·2 ± s.e. 8·2. Again for the 28 borou we have a significant correlation (+ 0·483) between notification-rates in 1942–44 and 1945–47. Figs. 3 and show the distribution of notification-rates, the areas high and low incidence being distinguished by shading.

For the examination of the effect of social factors t following variables were introduced into a multip regression analysis:

D, density of population.—In 1945–47 the measure us was the average number of persons per dwelling as deriv from the estimated figure for dwellings. For 1935–36 it w necessary to use 1931-census material; owing to the admitted unsatisfactory nature of the scoring of dwellings in the cen the same measure could not be used. Instead, the meas used was the number of persons per 1000 living at a dens of more than $1^1/_2$ persons per room.

S, social class.—1931-census figure for the percentage persons falling in social classes IV and V (semi-skilled a unskilled occupations). This is out of date, and the absolu social status of the boroughs has probably changed, but is less probable that their relative social positions hav changed, and as a very broad relative measure it was thoug permissible to use the 1931 figures.

N, nutrition.—Within a particular income level the nutritional standard might vary with family size, feeding habit, and educational standard. Therefore an ad-hoc nutritional inde was introduced—i.e., the percentage of school-children wh at routine medical inspection were graded as of subnorm nutritional standard.

If M = measles notification-rate per 1000 childre under the age of 14, we have to find the coefficient a, b, c, in the following equation

$$\mathrm{M} = (\text{a constant}) + a\mathrm{D} + b\mathrm{S} + c\mathrm{N}$$

so as to achieve the closest possible fit to the data. T results were entirely negative. The two equatio obtained were:

$$1935\text{–}36 : \mathrm{M} = 53{\cdot}6 - 0{\cdot}0093\mathrm{D} - 0{\cdot}074\mathrm{S} - 0{\cdot}27\mathrm{N}$$

$$1945\text{–}47 : \mathrm{M} = 52{\cdot}0 - 2{\cdot}1\mathrm{D} + 0{\cdot}043\mathrm{S} - 1{\cdot}1\mathrm{N}$$

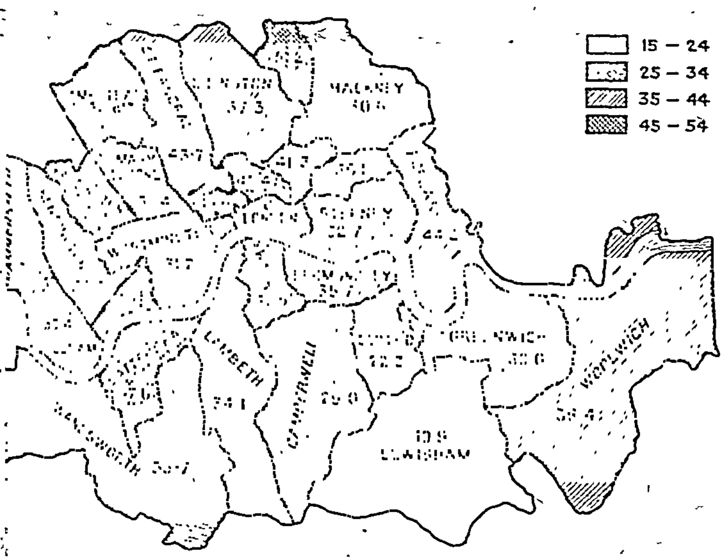
The partial correlation coefficients *involved* are s small as to be statistically insignificant. The tot regression accounts for only 6% of the inter-boroug variance in 1935–36, and only 10% in 1945–47. Th major cause of variation between the boroughs remain undetected by this analysis.

DISCUSSION

The periodicity of measles in London and in larg cities generally has been so regular and pronounced that it has been made the subject of considerable statistical study. One of the earliest of these was carried out by Hamer (1906), following up *the* then unpublished pioneer work of Thomas (1907). In essentials this postulated that, when the proportion of susceptibles in a densely aggregated community reached a certain *point*, a measles epidemic became a virtual certainty. The epidemic continued until a large proportion of those susceptibles had contracted measles and been converted into immunes.

---

* The data are set out in a multigraphed appendix, copies of which may be had on application to THE LANCET office, 7, Adam Street, London, W.C.2.



—Measles attack-rates in London Administrative County 1945-47 among children up to the age of 14.

ugh a considerable percentage of susceptibles was not cked. The low incidence of the subsequent year was ibuted to the immediate considerable decrease in eptibles, who then, continuously augmented by hs, gradually increased in numbers over a period of ghly eighteen months to the figure required to initiate rther epidemic. Hamer's work was carried further Soper (1929), who introduced the conception of sonal variation in "perturbing influences," and lysed the epidemic curves likely to arise from hyposes which took account of seasonal factors as well he accession of susceptibles.

oper's analysis went a considerable way (half-way his own estimation) towards explaining the vagaries he epidemic curve actually observed. In the discussion Soper's paper Halliday (1928) made the point that ography and rate of spread throughout an urban it must be taken into account:

> If the population was large, or if it was well-dispersed oughout space, measles in the form of outbreak had dom time to traverse the whole area before the refractory iod set in in May, the result being that annual outbreaks dominated. Such was the case for towns Paris and Edinburgh."

is true that the population of ndon, particularly the child popuion, was considerably rarefied during e war years in terms of persons per t area, but such dwellings as were cupied were not less crowded than fore, and when one considers shelter e and crowding in such schools as caped damage, there can hardly ve been less intermingling. By 1946 the latest the child population under e age of 14, though lower than before e war, had reached the 500,000 level, d there was considerable housing ortage involving crowding. One would ave expected a return to the pre-war pidemic rhythm. However, the facts bout the real disposition of the popuation during and after the war as gards spread of infection are difficult o elucidate, and the suggestion that alliday's theory might apply to warime London cannot be dismissed out f hand.

Speaking generally, the mathematical development of the law of mass action was supported by pre-war experience in London and played its part in enabling hospital authorities to foresee and plan in advance to meet their commitments. This statistical approach was in turn carried considerably further by others, including McKendrick (1940), who postulated a threshold density of susceptibles above which an epidemic became extremely probable. Hedrich (1933), from his study of measles statistics in Baltimore, has shown that, apart from seasonal variations in the years 1900–31, super-cycles of fifteen years or thereabouts also occurred. In his findings in Baltimore the immunes, or "intacts" as he prefers to call them, never fall below 32% or rise above 53%. Somewhat lower figures had been advanced by Thomas (1907) for infant classes in schools:

> "Measles tends to spread when an (infants') class accumulates unprotected members to the extent of 30–40%, and when spread has begun it continues until the proportion is reduced to 15–20% protected."

Stocks and Karn (1928), as a result of a very thorough examination of the incidence of measles in the borough of St. Pancras, introduced a novel explanation not only of the periodicity, but also of the still more challenging fact that epidemics end even though many susceptibles appear to remain unaffected. This was that during an epidemic a process of temporary latent immunisation by means of subclinical attacks was set in motion in the proportion of roughly 1 clinical case to 4 or 5 temporarily immunes, this temporary immunity enduring only for about eighteen months or two years—i.e., until the next epidemic. Halliday (1928) in Glasgow put forward the same idea.

In contrast with the purely statistical approach is the theory of parasite variation associated with the names of Brownlee (1909) and others who believed that the rôle of the parasite was much more important than that of the host. In this view periodic fluctuation in the infecting power of the virus was the factor chiefly concerned. At the beginning of an epidemic the power

SOCIAL CONDITIONS

If the incidence of measles has in fact fallen since 1938, some cause must be sought for the decline. It is natural to turn first to the examination of the possible effect of social conditions on the incidence of measles, so that changes in such conditions during and since the war may be given adequate consideration in resolving this problem of discovering a cause for the lowered incidence of measles.

The County of London is split into 28 metropolitan boroughs (ignoring the City of London, which for this purpose has too small a resident population to be of value), each with different social characteristics, and an intercomparison of these characteristics in relation to the incidence of measles should indicate the rôle of environment factors if these exist. The investigation was made over two periods: 1935–36, and 1945–47. For the earlier period school reports provided the evidence of incidence, whereas for the later period statutory notifications were available.*

In the pre-war period of two years, 1935–36, average annual attack-rate ranged from 28·1 "equival notifications" per 1000 of population under the ag 14 (in Holborn) to 62·6 (in Stoke Newington). T mean rate for the county was 46·5 ± s.e. 7·8. T the incidence in certain areas tended to be consisten high or low is indicated by the statistically significa correlation (+ 0·582) between incidence in 1935 and incidence (on the same statistical basis) in 193 for the 28 London boroughs.

In the post-war period of three years, 1945–47 (th is no biennial swing to favour a two-year period) t average annual notification-rate ranged from 19 p 1000 of population under the age of 14 (in Lewish to 51·2 (in Stoke Newington), with an average for t county of 38·2 ± s.e. 8·2. Again for the 28 borou we have a significant correlation (+ 0·483) between t notification-rates in 1942–44 and 1945–47. Figs. 3 and show the distribution of notification-rates, the areas high and low incidence being distinguished by shading

For the examination of the effect of social factors t following variables were introduced into a multi regression analysis:

D, density of population.—In 1945–47 the measure u was the average number of persons per dwelling as deri *from the estimated figure for dwellings.* For 1935–36 it w necessary to use 1931-census material; owing to the admitted unsatisfactory nature of the scoring of dwellings in the cen the same measure could not be used. Instead, the meas used was the number of persons per 1000 living at a dens of more than $1^1/_2$ persons per room.

S, social class.—1931-census figure for the percentage persons falling in social classes IV and V (semi-skilled a unskilled occupations). This is out of date, and the absol social status of the boroughs has probably changed, but is less probable that their relative social positions ha changed, and as a very broad relative measure it was thoug permissible to use the 1931 figures.

N, nutrition.—Within a particular income level the nut tional standard might vary with family size, feeding habit, a educational standard. Therefore an ad-hoc nutritional ind was introduced—i.e., the percentage of school-children w at routine medical inspection were graded as of subnorm nutritional standard.

If M = measles notification-rate per 1000 childr under the age of 14, we have to find *the coefficien* a, b, c, in the following equation

$$M = (\text{a constant}) + aD + bS + cN$$

so as to achieve the closest possible fit to the data. T results were entirely negative. The two equatio *obtained* were:

$$1935\text{–}36 : M = 53{\cdot}6 - 0{\cdot}0093D - 0{\cdot}074S - 0{\cdot}27N$$
$$1945\text{–}47 : M = 52{\cdot}0 - 2{\cdot}1D + 0{\cdot}043S - 1{\cdot}1N$$

The partial correlation coefficients involved are small as to be statistically insignificant. The tot regression accounts for only 6% of the inter-boroug variance in 1935–36, and only 10% in 1945–47. Th major cause of variation between the boroughs remai undetected by this analysis.

DISCUSSION

The periodicity of measles in London and in larg cities generally has been so regular and pronounced th it has been made the subject of considerable statistic study. One of the earliest of these was carried out b Hamer (1906), following up the then unpublished pione work of Thomas (1907). In essentials this postulate that, when the proportion of susceptibles in a densel aggregated community reached a certain point, a measl epidemic became a virtual certainty. The epidem continued until a large proportion of those susceptible had contracted measles and been converted into immune

Poliomyelitis

uring the week ended Sept. 17 notifications in gland and Wales were: poliomyelitis 311 (284), oencephalitis 31 (22). These are the highest weekly res recorded this year. Figures for the previous week shown in parentheses.

ultiple cases (poliomyelitis and polioencephalitis ether) were reported from the following counties: don 41 (31), Berkshire 7 (4), Chester 4 (6), Cornwall (3), Devon 5 (5), Dorset 3 (5), Durham 7 (7), Essex (16), Gloucester 15 (10), Hertford 4 (5), Kent 16 (9), caster 29 (38), Leicester 13 (7), Lincs, Kesteven 5 (2), cs, Lindsey 7 (1), Middlesex 25 (19), Norfolk 3 (1), [illegible]). Northumberland 10 (8), Nottingham [illegible] 8 (3), Southampton 10 (15), Stafford [illegible]). Sussex, East 2 (4), Warwick 10 (10), [illegible] orks, East Riding 5 (4), Yorks, North [illegible] s, West Riding 33 (25), Glamorgan 3 (7).

n 1947 the total figures for the corresponding week e poliomyelitis 572, polioencephalitis 42; and in t year this was the week in which the fall in tifications began.

Treatment of Smallpox

In the September issue of the *Monthly Bulletin of the inistry of Health and the Public Health Laboratory rice*, Dr. D. F. Johnstone and Dr. J. L. Fluker suggest following scheme of treatment for confluent and morrhagic smallpox: (1) not less than 0·5 mega-unit penicillin should be injected intramuscularly at least ur times daily; (2) when the vesicles become umbili- ted or their contents turbid, 1 g. streptomycin should administered intramuscularly each day, and the daily se of penicillin should, if necessary, be increased to 5 mega-units; (3) streptomycin should be continued r about a fortnight, or anyhow till the lesions have ecome well dried; and the penicillin until the majority f the scabs have separated. With discrete or modified uptions streptomycin would seem unnecessary: but, o reduce suppuration, penicillin should be given in out half the above dosage for a fortnight or so.

In England Now

A Running Commentary by Peripatetic Correspondents

As the congress season closes I find, to my regret, that there was one to which I was not invited. "The Doctors, Friends of Wine" met under distinguished patronage in Bordeaux.[1] (I have in the past assisted at symposia in places so remote as Crewe Station and Calcutta whose activities might have deserved this title; but, somehow, we never thought of it at the time.)

Œnotherapy was the keynote of the Bordelaise gathering, and the conclusion, "that wine is the best weapon with which to fight alcoholism," hints at homœopathy too. Other credit lines for grape-juice were its phosphorus content (and no-one, as far as I can learn, suggested match-heads as a substitute); its internal use by all French athletes of the front rank: and—wait for it—its powers of sterilisation when added to water of doubtful purity. I am indeed glad to know that this old wife was there to tell her oft-told tale. Was not the traditional valour of the poilu supported by the huge horse-drawn tun, good for morale and a precaution against typhoid? In spite of personal experience of vintages which would kill *Salmonella typhi* as surely as Mrs. Knox's sherry would burn the shell off an egg, I fear that this short way with bacteria must join chalybeate springs and the monaural stethoscope in the tail-pocket of a frock-coat. Quite bluntly, I suspect this congress of being no more than a most enjoyable occasion to boost the wine trade, and I sympathise with those of our French colleagues who have regretted its publicity, the more so since there are parts of France where alcoholism is still the problem which it was here fifty years ago. But if I am mistaken, and the purpose of the organisers was the encouragement of œnophily among the faculty, I would make so bold as to suggest that for those of us whose invitations went astray they adopt the traditional method of distributing samples. My choice is two dozen of Ch. Ausone 1924; magnums will do.

* * *

Your Peripatetic may well be right to suggest there is no overdose for Art Therapy. But I know of one absolute contra-indication. The clinical picture goes something like this: "Hello, going painting today, Daddy?" "Fathead, Daddy can't paint. He just mucks about with paints." "Anyway, I'm coming with him. I feel just like a bit of painting." "So do I." (*Rep.*, up to size of family.) "We'll want some of your paper, Daddy." "I can't fix my paper down." "Have you got a pencil, Daddy?" "Will you sharpen my pencil?" "Oh! bother, my water's upset, can I have some more?" "Hello, what's that supposed to be, a rock?" "Silly fathead, its a cow; even Daddy isn't as bad as that." "You've nudged me and made me smudge," "No I didn't." "Ow, stop pinching," "I've finished." "Good lor, call that a picture." "I've drawn a wizard speed-boat in mine." "There isn't a speed-boat there." "I've drawn a tank-landing craft." "Can I have some more paper, Daddy?" "Come on Daddy, and play beach cricket."

In twenty years' time, if I last that long, I'm hoping to try the effects of art therapy. But then I have no doubt it will be: "Hello, going painting today, Grandad?"

* * *

"It is the country doctor who is taking the place of the parson as the skilled grower of plants. There is something about the profession of medicine which peculiarly fits a man, if he can only find the time, to become a good gardener." The operative words may now be "if he can only find the time." However, those who are already gardeners will certainly enjoy Dr. Denham's amusingly written, sound, yet sceptical book.[2] My only quarrel with it is that he knows too much. Should you think of planting willows for winter effect, you can imagine him saying "Do you intend *Salix vitellina, S. britzensis, S. cardinalis, S. decipiens, S. purpurea* or

of the virus to multiply and establish itself on fresh hosts was suddenly increased. These powers, exalted by rapid passage, mounted to a maximum, until as a result of increasing resistance or other factors the impetus of the attack died down and the epidemic subsided.

How do these theories meet the facts of the present situation ? It must be accepted that the purely statistical hypotheses seem inadequate. In London today the ratio of susceptibles to immunes (1 : 1) stands at an appreciably higher figure than it stood for many pre-war years (0·75 : 1). If an epidemic of measles depended solely on a purely mathematical relationship of this sort, it is only reasonable to expect that we should have had a really large epidemic at any time during the past few years.

Stocks and Karn's (1928) theory, if novel, is reasonable and attractive, and it is to some extent in line with modern views and work on other diseases, such as diphtheria and poliomyelitis, but it does not explain the present situation satisfactorily, unless we are to postulate that latent immunisation has been progressing on a much wider scale since the war than the proponents of the theory themselves envisaged. Their theory is open to several serious objections. First, it does not tally with hospital experience. In ward outbreaks (London County Council 1933), for example, it not infrequently happens that a child may withstand three successive exposures to measles at fortnightly intervals, only to succumb to a fourth. It is difficult to see how this could happen if the latent immunising mechanism envisaged by the theory were in operation. Again, why should active immunity, acquired by repeated exposure or subclinical attacks, sufficient to withstand an average infecting dose of virus disappear so rapidly, seeing that immunity, as established by a clinical attack of measles, is normally so solid and durable ? Indeed, why should not the latent immunising process resume where it left off in the next epidemic, at least as often as it breaks down, to consolidate immunity, and thus produce a far higher percentage of persons who escape measles altogether ? In the case of poliomyelitis, during epidemics of which we believe a comparable mechanism to operate, the proportion of those who develop paralytic attacks at any time is infinitesimal compared with those who escape. In measles the situation is reversed. Panum (1846), in the celebrated epidemic in the Faroes, estimated that 99% of the population was attacked, and Paterson (1882) quotes Gudmunsson as giving a similar percentage for the epidemic in Iceland. Hedrich (1933) exhibits a composite graph, based on the work of Butler for Willesden ; Henderson for London, Ontario ; Collins for four United States cities ; Sydenstricker for Hagerstown, Md. ; and his own work in Baltimore, to show that 95% of children have developed measles by the age of 15, and Stocks (1949) has estimated that by the age of 10 years 70% of the children in St. Pancras have had measles. It is therefore understandable that hitherto the host-parasite reaction in measles should have been regarded for the most part as an example of the all-or-nothing law, the host either developing an attack in response to infection or exhibiting no reaction at all. But, even if we concede Maxcy (1948) his 5% of "subclinical" immunes in preference to the concept of "natural" immunity (to account for the 5% who never develop a clinical attack), it seems that the concept of temporary immunisation, neatly as it would solve our difficulties, must be regarded with considerable reserve until work with the virus, including a satisfactory test for susceptibility or immunity, has made the necessary progress.

The same must be said of the theory of virus variation which Stocks (1928) has dismissed, though he postulates as an essential prerequisite to outbreaks sudden fluc tions in apparent infectiousness, which could not wholly explained by immunity changes (as could ensuing course of the epidemic) and must be attrib to changes in facility of transmission. It is true virus variation may too readily be invoked to exp anything and everything, but it is surely as logical regard this increased "facility of transmission" function of the virus, accelerating the dynamic infection, as of equally vague meteorological fact as Stocks has done. Wells's (1944) demonstra of the close correspondence between the "closed-win period" of reduced ventilation and the peak of mea prevalence in the United States appears convincing, would explain the occurrence of a winter epidemic w susceptibles were abundant ; but these conditions h recurred every winter since 1940, whereas mea epidemics on the scale expected have not. Never ind were windows more tightly closed than in the ar weather and fuel shortage of the first three month 1947 ; overcrowding was acute, susceptibles w abundant, and the infection was present, but no epidemic materialised in London. We reserve opinion, remembering that strain-variation is w known among those viruses already sufficiently studied variola major and minor, poliomyelitis, infective hepati and influenza. To assume that only one strain of meas virus exists, or that all strains yet to be identified w exhibit a common level of infectivity, seems to unwarranted.

Possibly yet another factor may enter into t calculation—the widespread improvement in ch nutrition that has taken place since 1940. In gene the nutritional state of the individual has not be shown to exert any appreciable influence on the dete mination of virus infections. The evidence is scant, but such as it is it tends to show that virus, as an oblig cellular parasite, is sometimes more likely to attack th well than the poorly nourished. This was exemplified b the deaths in the pandemic of influenza in 1918, and ha often been noted as regards poliomyelitis in the U.S. Indeed there is suggestive evidence to show that th poliomyelitis virus will not attack the central nervo system in some hosts unless certain B-group vitamins a present in the neurones (Rasmussen et al. 1944, Lichst et al. 1946). Foot-and-mouth disease in cattle is a we known example in which the better the animal's nutr tional state the more likely it is to be attacked (Green 194 On the opposite side of the account there is the exampl typhus, a rickettsial disease, in which, by common con- poor nutrition is regarded as a predisposing factor, an rickettsiæ are now known to share many of the chara teristics of virus. As regards measles, however, it is fa to say that nutritional state has never been shown t exert any influence on the likelihood or otherwise of a attack, and its pre-war universality, whether in publi private, or elementary schools, or in slum distric compared with better-class residential suburbs, reinfor this conclusion, which is borne out in the regressio analysis mentioned above, and as follows, where th difference is not statistically significant :

	Notifications per 1000 of childr up to the age of 14 1945–47
Boroughs with a nutritional standard :	
above average (*a*) ..	3·37 (s.e. 0·025)
below average (*b*) ..	3·12 (s.e. 0·036)

(*a*) Seven boroughs with less than 5% of children graded a school inspections as nutritionally subnormal.

(*b*) Five boroughs with more than 8% of children graded a school inspections as nutritionally subnormal.

Finally, the experimental administration of vitamins A and D to measles patients in 1934 had no significant effect (Mackay et al. 1936), suggesting that measles patients are not subnormally nourished.

after he has been pushed down "the slippery slope leads to the department of psychiatry"!

is really amazing how little some patients know it their "case" after prolonged stay in hospital: it commonplace to discover an abdominal scar whose er does not know what was done at the operation. man who leaves his car at a garage for repairs ılly insists on knowing what has been done before he s the bill. But the hospital patient has never had feeling that he pays the bill, in any sense; he has ays received medical treatment as a sort of charity.

ven now, as I observed afresh when I was recently a ient in a general surgical ward, his attitude towards medical staff is one of almost feudal humility—he ıld never dream of calling them to account for their ıgs. At most, his self-assertion is sulky, truculent, perplexed. He feels defeated before he starts any test, for it is THEIR hospital; THEY make all the rules he is only there on sufferance.

is doubt and uncertainty is, of course, further eased by anxiety: the fear of some terrifying positive wledge makes him readier to accept vagueness or porising on the part of his doctors, and he may also ıtally repress or falsify information they give him if s too painful to contemplate. To have one doctor marily responsible for him throughout his stay in pital would tend to minimise these fears, for a good port would more easily be achieved.

f the patient were not so often treated by "birds of sage," he would be less liable to become, himself, a d of passage from department to department, and m from hospital to hospital.

ondon, W.1. F. R. C. CASSON.

SIR,—While entirely agreeing with Dr. Lipscomb's me that there is often a failure of medical coordination handling patients who come to hospital, I do not think at all his remedies should be accepted.

He suggests that it should be the first assistant's duty reassure the patient. Should this not be the duty of e chief under whose care she is supposed to be? Is t his reassurance and explanation likely to be far more vincing than that of anyone else, and cannot the tient reasonably expect to hear direct from him? And it not utterly deplorable if the only contact she has th the chief is on one occasion when this "important ntleman visits her with great ceremony and a numerous inue"? If he does no more than this, should he not e up the pretence that she is his patient?

Dr. Lipscomb's statement that "if he [the clinical assis-nt who first saw the patient] could not make a diagnosis the evidence available in the outpatient department, s duty was to admit the patient to hospital for further estigation" should also not pass unchallenged. Why ould someone with symptoms of the kind being con-dered enter hospital at all? Even if it is not thought at many of the investigations done on these patients, ch as gastric analyses and, as a rule, cholecystograms, e quite futile, why cannot they all be done in the tpatient department? Does not the very fact of the atient's being admitted suggest to her that she must ave something seriously the matter and thereby direct er to "the slippery slope that leads to the department f psychiatry"?

Farnham, Surrey. J. W. TODD.

THE EMPLOYMENT OF ELDERLY PERSONS

SIR,—Your leading article of Sept. 10 mentions the importance of activity in the aged. Dr. Sturdee (Sept. 17) says that in the investigation of the most suitable forms of activity and employment for elderly persons, general practitioners, district medical officers of health, and factory medical officers can make the most valuable contributions. Probably studies in this field may bring benefits as far-reaching as those that have resulted from the work of school medical officers in the field of preventive pædiatrics.

Although the aged sick in hospital form only a small proportion of the aged community, the opportunities in hospital for continued observation and the availability of occupational therapy allow those caring for these people to make some suggestions. The incentive to recovery in the aged sick with their long-term illnesses is often absent, yet without an incentive all medical efforts directed towards their rehabilitation are futile. Occupational therapy of the diversional kind helps many to forget their disabilities, but the prospect of a future spent in making articles of the "arty-crafty" type can hardly provide a sufficient inspiration for the patient's further existence. Occupational therapy must therefore be developed along vocational rather than diversional lines, and the patient should be taught a job which he can usefully carry on after his discharge from hospital. Vocational training is successfully applied to the rehabilitation of the younger disabled person, but little has been done in this direction for those suffering from the disabilities of old age. In considering the occupation most suitable for the aged patient, there must be coöperation between hospital doctors and local employers. In this way the type of work available can be ascertained and those patients suitable for this work selected. One example of employment which can be learned in hospital and carried on after discharge is the assembly from component parts of small mechanical articles; boxes of components are collected from the factory and their assembly is paid for on a piece-work basis.

We must, however, always remember that while there are some for whom a design for employment is possible, there are others for whom old age brings enforced leisure. Whether this leisure becomes an intolerable burden or a source of happiness depends largely on individual education and the variety of interests acquired during a person's working life.

FOREIGN BODIES IN THE ABDOMEN

SIR,—There is a widespread belief in medicine that unusual cases will present in a series of two or three within a short time of each other. Mr. Travers's article in your issue of Sept. 10 was noted with interest and the following case is reported because it was seen so soon afterwards.

The patient, a woman, aged 63, was admitted to hospital on Sept. 15 with a history of acute colicky lower abdominal pain for some thirty-six hours. The pain continued in spasms, particularly if any fluid or solid food was taken. There was no nausea or vomiting. Within a few hours the pain spread over the lower abdomen as a constant ache and subsequently became generalised.

On admission the general condition was excellent. The breath was normal and the tongue clean. The abdomen showed the signs of a general peritonitis with maximum tenderness below the umbilicus. In view of these findings, a diagnosis was made of peritonitis of unknown cause and laparotomy was carried out through a right paramedian incision.

A small amount of seropurulent fluid was found on opening the abdomen. The appendix and the uterus and appendages were normal, but on examination of the small bowel some loops which were brought out of the pelvis were found to be covered with purulent exudate. The sigmoid colon was palpated and a sharp object was felt projecting through the medial wall near the apex of the sigmoid loop. With retraction the area was visualised and the foreign body was seen to be a fish-bone. The paramedian wound was closed and a left oblique muscle-splitting incision made and the colon with the foreign body delivered externally. It was impossible to withdraw the bone through the perforation and the colon was opened, the bone removed, and a Paul's tube inserted.

S. daphnoides ?" But don't be put off—you can work off his knowledge on your friends. One minor department of gardening has been omitted from his chapter on garden tools: he has said nothing about the application of the tools of other disciplines to gardening. In my household nearly all the kitchen implements disappear into the garden—gravy strainers, sieves, carving forks, kitchen scissors, and spoons all gravitate to the gardening trug. The double saucepan is useful for sterilising small quantities of earth; and I recommend the steak tongs for people who are squeamish about picking up those long black slugs which pullulate after rain. Recently I came into a small legacy which included the very out-of-date implements of a surgically minded practitioner. Of course the scissors, scalpels, forceps, and the like were accepted with joy, but I'm puzzled to find a use for a laryngoscope. I don't grow pitcher-plants. Perhaps other Peripatetics have found the answer? And obstetrical forceps? Anything doing with vegetable marrows?

* * *

Whenever a policeman on point-duty raises a minatory forefinger at me and halts my car, I wonder whether I should have been let past if I had one of those DOCTOR windscreen labels. He might think I was dashing urgently to operate, à la Walter Mitty, on a case in which Corcopsis had set in.

On the other hand, such a label might render me liable to be stopped for any and every minor road casualty, and give me the embarrassment of admitting that I'm only a psychiatrist, not a *real* doctor, and it would surely stimulate car thieves to ransack my car for phenobarbitone.

What I should really like would be an assortment of rear-window signs, controllable from the dashboard, which could be flicked into view p.r.n. There are so many occasions when one would like to flash a message to the driver behind: sometimes apologetic, "Sorry I cut in"; sometimes curt, "No use your hooting!"; or, simply, "Temper!"

* * *

After six months of Casualty in a London hospital, I resolved to take my students for a farewell session at the local. It was disconcerting to find a preponderance of total abstainers—the explanation offered was that most of the Demob Types had burnt themselves out in the Forces. The remaining 10% had a small ulcer on his lesser curve which he nursed with tender care. We finally repaired to the milk bar down the road, where we chatted softly together of this case and that, until chairs were stacked on all the other tables and we reluctantly dispersed.

We had spoken with reverence of Mrs. A., whose chest was always settling on her stomach—it was her husband who died of Hogskin's disease; he had attended for a long time with Gastric but they never diagonised him. Of old Miss B, who was always full of wind which came out continually through her left ear, and was only too willing to dilate on the horrors of her miscarriage, which apparently occurred at two and a half minutes. And there was the brisk housewife who wanted some M & B's for her chicken which had the diarrhœa. It was in Casualty, too, that my test for neurosis—the Raving Matrices—was first used successfully. This consists in listening to the patient talk for fifteen minutes, after which you take your own temperature. A rise of 0·6°F or more puts the issue beyond doubt. The sweet young refugee who said she had been working in Hungary as a typewriter was rapidly followed by the elderly gent who had the blood-pressure every half-hour. "I am feeling very middling indeed," said a third, "I take confection of senna, but it hangs about in my neck." Lastly there were the notes made by my irritated predecessors at the end of the day and their tether, such as "Delighted to say he is worse. O.E. much better"; or this tribute to the vis medicatrix naturæ: "May '46, terrible headaches, impossible to live." "June '46, still alive."

When I retire from the fray, somewhat pottery in the legs, when I have written my last certificate for Natural Health and prescribed my last Peninsular Tablet, these are the memories *I* shall take out of medicine.

Letters to the Editor

SEEING THE PATIENT THROUGH

SIR,—Would Dr. Lipscomb, I wonder, accept an ame ment to his thesis? It is that the hospital's duty is really to see Mrs. A through but to help Dr. B to her through. It is this which, in my experience, hospi find so very hard to do.

Dr. B has, of course, reciprocal duties which h unlikely to recognise unless he feels the patient to be own, and which he cannot perform without time perform them in. Time he must have, to take a pro history and to talk to Mrs. A, and he must pro unceasingly until he gets it; but, given only this ti three obligations appear to rest with him: to ref from calling in the hospital if history plus consult room examination can yield a diagnosis; to explain Mrs. A, if he sends her, what he is asking of the hospi and what, in round terms, she may expect there; and write the hospital a letter.

The last two of these duties are far more diffic than the first. Both are relatively easy if he can se Mrs. A to a physician and a hospital he knows well, b this cannot always be done. Consultation clinics wi named physicians attending at published times are ve helpful, but even then the physician is not always th on the day and sometimes the patient must be se simply to a hospital, when it may be hard to know whom to write. It would be a help if the appropri authority would tell us precisely what hospital offi will receive our Mrs. A and the letter we send with h

Dr. Lipscomb deals faithfully with the next part the story, painfully familiar from the lips of patient and we come to chapter III, the patient's return. It less common than it was to get no report at all; b it is still common to get none for many weeks, a a human letter to balance the human letter sent wi the patient is really rare. I think it is getting rare because the report usurps its place.

Dr. Lipscomb's sketch report is quite typical. I sends Dr. B's heart into his boots and makes hi ashamed to face his patient. It implies in every line tha Mrs. A is a mere aggregate of bodily mechanisms a that to grant her a mind or personality, unless by calli her "a somewhat neurotic type," would be a betray of medical science. It attempts no positive answer t the problem of her symptoms. Mrs. A and Dr. B lo sadly at each other. "Of course everyone was v kind"; but the consultation has been a failure and sh must start again.

But the failure is not a failure to "see her through Dr. B wanted her back and we may hope she wished t come back to him. He called in the hospital as a co sultant and collaborator, and the conscientious who "has Mrs. A up again," as though she were no his patient, forgets that pretty piece of etiquette where the consultant enters the bedroom last but leaves first. Dr. B will see her *through*. It is his job and no-o else can, or should try to, do it for him. But there w a point at which he needed such *help as only the hospit* could supply, and the hospital has not *understood* t nature of the problem and has missed its chance.

Dr. Lipscomb suggests that hospitals and *practitione* should get together, and that is indeed something a getting together of hospital doctors, family *doctor* and experienced patients—all being *homines bo* *voluntatis*—would be more than something.

LINDSEY W. BATTIS

London, N.W.3.

SIR,—The dubiety created in the mind of the averag hospital patient by the medical incoördination D Lipscomb describes is, alas, often *realised only by tho* dwellers in the infernal regions who have to deal wi y criticisms are mainly directed against London, less against the provinces. The causes for this of balance and proportion in selecting cases are erous, and many are charged with great emotion. criticism raises outbursts of indignation, some ified, some not. The causes do not lie entirely with hospitals but partly with those who send patients to n.

EIDON.

R,—We read a great deal these days about suggested ses in general practice and even about the formation hairs in general practice. Some even go so far as to e that general practice is not taught to graduates or ergraduates and call for a commission of inquiry. sonally I attribute such lines of thought to the times which we live: some are not happy unless they note a course for this, that, and the other. But ly it is the personality of the doctor that makes nars his calling. Do the advocates of courses really eve that these, per se, will transform an unsatisfory practitioner into a conscientious, a tolerant, and eloved family doctor?

verpool, S. JOHN R. MACINTYRE.

RESEARCH

IR,—Your leading article of Sept. 3 stated that had not yet heard of a board of governors of a ching hospital using the free funds at their disposal the promotion of research. At University College spital the board of governors have allotted a block nt of £5000 for the provision of a metabolic unit, and addition they have asked the medical committee to mulate a scheme for utilising a further grant of £5000 annum for research purposes.

niversity College Hospital,
London, W.C.1.

T. F. W. MACKEOWN
Administrator and Secretary.

CHLOROMYCETIN IN ENTERIC FEVER

IR,—By a happy coincidence a little chloromycetin ame available simultaneously with the admission to s hospital of 4 cases of enteric fever. The effect of s drug was in each case immediate and incontestable.

ASE 1.—A baby boy, aged 18 months, was admitted on ne 15 this year with a three-day history of high fever and vulsions. The abdomen was distended; scattered rhonchi re heard over both lungs; and the fauces were injected. nicillin 25,000 units was injected four-hourly; and the t day sulphadiazine 0·25 g. four-hourly was added. lture of stool was negative for the typhoid group; and on 18th blood-culture also proved negative. On the 20th, wever, blood-culture yielded *Salmonella paratyphi-B*.

On the 21st all other treatment was stopped and chloroycetin, mixed with a little sugar and sour milk, was begun doses of 0·125 g. four-hourly. Twenty-four hours later the tient's general condition was much improved; on the rd stool-culture revealed no organisms of the enteric group; d on the 24th urine-culture was negative. On the 27th e Widal reaction was positive 1 : 125 for *S. paratyphi-B*. n the 28th chloromycetin was stopped, altogether 4·5 g. ving been given.

On the 30th the parents removed the child from hospital. n July 20 he was reported well, and stool-culture was gative.

CASE 2.—A boy, aged 5 years, was admitted on June 27 ith a history of fever for the past ten days. Two days reviously the Widal reaction had proved positive 1 : 50 for . *typhi*. The spleen was enlarged two fingerbreadths below he costal margin; roseolæ were numerous over the abdomen nd sparse over the chest and thighs.

Chloromycetin was begun in three-hourly doses of 0·125 g. By the 28th the general condition had improved and the roseolæ had faded. On the 30th blood-culture yielded *S. typhi*. On July 3 the patient was convalescent, and chloromycetin, of which altogether 5·75 g. had been administered, was stopped. On the 4th the Widal reaction was reported positive 1 : 125 for *S. typhi*.

On the 7th the patient left hospital. Cultures of blood, urine, and stool were now all negative for the enteric group. On the 23rd the child was reported well; stool-culture remained negative.

CASE 3.—A man, aged 45, was admitted on July 16. Fifteen days previously he had vomited and since then had been feverish: for the last four days the stools had contained dark blood. The patient was very toxic and distressed, and since the diagnosis seemed certain chloromycetin was begun immediately in doses of 1 g. hourly for four hours and thereafter 0·5 g. four-hourly.

On the 17th his general condition was improved. On the 18th the Widal reaction was found to be positive 1 : 25 for *S. typhi*. On the 22nd urine-culture was negative. By the 24th the patient was convalescent; there had been no melæna since the second day of treatment. Chloromycetin was stopped after a total of 22 g. had been given. On the 26th stool-culture revealed an organism with all the characteristics of *S. typhi* except motility, which was impaired.

On the 29th the patient, saying that he was cured, insisted on leaving hospital. On the 30th stool-culture proved negative for the enteric group. On Aug. 1 he was reported to be well: blood-culture was negative.

CASE 4.—A boy of 12 was admitted on July 25 on account of high fever and prostration which had been evident for the past week. Prostration was extreme, and the spleen was enlarged three fingerbreadths below the costal margin: there were no roseolæ. On July 26 blood-culture proved positive for *S. typhi*.

On the 27th chloromycetin was started two-hourly in amounts of 1 g. for the first three doses and of 0·25 g. thereafter. On the 28th his general condition was much improved. On the 29th blood-culture was positive for *S. typhi*: stool-culture was negative for the enteric group. On Aug. 1 urine-culture was negative; the Widal reaction was positive 1 : 250 for *S. typhi* (*H*). On the 2nd blood-culture proved negative; the spleen was much reduced in size. By the 4th the patient was convalescent; chloromycetin was stopped, altogether 20 g. having been given.

On the 5th the spleen was only just palpable and stool-culture was negative; the patient left hospital.

In each of these cases improvement with chloromycetin was immediate and sustained; in case 3—a severe one that without chloromycetin would have caused anxiety for weeks—the melæna was arrested within forty-eight hours.

In Syria enteric fever is endemic and often very severe; in both children and adults hæmorrhage and perforation often caused death despite immediate hospital treatment. Unfortunately the price of chloromycetin is at present almost prohibitive.

Altounyan Hospital, Aleppo, Syria. Y. KILEDJIAN.

SIR,—Two cases of typhoid fever have lately been treated with chloramphenicol ('Chloromycetin') at the Government Isolation Hospital, Amman.

CASE 1.—A girl, 12 years old, weighing 45 kg., was admitted on Aug. 6, having been ill for the past thirteen days. She was stuporose, and clinically her condition was typical of toxæmic typhoid fever; the Widal reaction was positive. Chloromycetin therapy was started on Aug. 8 (the fourteenth day of the disease) with 2·25 g. followed by 0·25 g. two-hourly until the patient became afebrile, after four days. Then 0·25 g. was given four-hourly for five days. The total dosage was 17 g. The patient was discharged cured on Aug. 22, and so far no relapse has been reported.

CASE 2.—A girl, aged 18 years, weighing 30 kg., was admitted on Aug. 4, with a history of nine days' illness. The clinical diagnosis of typhoid fever was confirmed by a positive Widal reaction. Chloromycetin therapy was begun on the 7th—the twelfth day of the disease. The effect was not as dramatic as in the first case; the temperature took longer to become normal, but improvement was apparent. The initial dose of 2·5 g. was followed by 0·25 g. two-hourly until the temperature was normal on the 19th—after twelve days' treatment, compared with four days in the first case. For the next five days 0·25 g. was given four-hourly. The total dosage was 49 g. After a further six days' observation, the patient was discharged on the 24th. So far there has been no relapse.

DJAMIL FAIK TUTUNJI
Amman the Jordan. Under-Secretary of State for Health.

The bone was found to measure about 2 in. long expanding at the base to $^1/_2$ in. wide. The immediate postoperative period has been satisfactory and the temporary colostomy will shortly be closed.

A detailed history taken from the patient after operation shows that she had eaten some plaice about five days before the onset of the pain. Her lower dentures were uncomfortable and she had left them out for that particular meal and believes it was easily possible for her to have swallowed the bone without noticing it. In view of the size of the bone it is surprising that it could negotiate the narrow terminal ileum. The sigmoid loop was much less mobile than normal and this may have been the cause of perforation at this level.

Central Middlesex Hospital,
London, N.W.10.

C. F. CHAPPLE
W. B. MCGOWAN.

SIR,—The *article* by Mr. Travers (Sept. 10) *and his* request for further reports prompts me to record the following two cases:

CASE 1.—On Dec. 31, 1943, a woman, aged 57, was admitted to hospital complaining that five days previously she had had sudden onset of acute upper abdominal pain, which had steadily become worse. On admission her temperature was 101·2°F; pulse-rate 104 per min., blood-pressure 85/60 mm. Hg. Examination revealed epigastric rigidity and tenderness, and on pelvic examination a severely eroded pessary was removed, accompanied by fæcal discharge. The signs indicated an acute inflammatory lesion in the upper abdomen, and the primary site of infection was thought to be in the pelvis.

At laparotomy, after careful preoperative treatment, a high right paramedian incision was made, and on opening the abdominal cavity a grossly œdematous falciform ligament presented. The right side of the liver and the gall-bladder appeared normal, but to the left of the falciform ligament the liver was plum-coloured. On dividing the falciform ligament an abscess cavity about $1^1/_2$ in. in diameter was opened and typical *Bact. coli* pus escaped. The exploring finger palpated a sharp object on the right wall of the abscess, which on removal was seen to be a portion of a rabbit rib. This measured $1^1/_2$ in. in length; the sharp end was bevelled, giving it the appearance of a bent aspirating needle. The abdomen was closed with drainage without exploring the pelvis. Postoperatively there was much discharge, but recovery was uneventful and the fæcal fistula healed spontaneously.

Of particular interest is the fact that the patient volunteered that two months previously she had had a similar attack of acute abdominal pain which was intensified on any thoraco-abdominal movement, particularly flexion. Presumably this was the time when the bone perforated the pylorus. In the few days before her admission the patient experienced the same postural intensification of pain. The description she gave was convincing.

CASE 2.—Early in January, 1944, a woman, aged 35, was admitted with acute right-sided abdominal pain. The clinical picture was not clear and a provisional diagnosis of acute cholecystitis was made with subsequent expectant treatment. The patient had been admitted some months previously for an abortion, which was dealt with without incident, but one physician noted at that time that the spleen was palpable. During the days of observation the consultant surgeon was asked to see the case, but no definite diagnosis was made. The liver became palpable and gradually increased in size, eventually reaching the right iliac fossa. The patient aroused considerable interest among the medical staff and many investigations were performed with normal results. However, on further careful questioning the patient gave the information that the pain was intensified on movement, particularly flexion. Up to this time laparotomy was considered unwise, but in view of the case already described the many radiographs were re-examined and revealed the distal half of a broken pin or needle lying on the deep surface of the anterior abdominal wall. Laparotomy followed, with a provisional diagnosis of hepatic abscess.

At operation the metallic body was found on the deep surface of the rectus abdominis, and *just deep to this on* opening the abdominal cavity the free margin of the liver *showed a triangular scarred area* $^1/_2$ in. across the base. was excised. On further exploration the right side of liver was seen to be almost filled by a firm, rounded, mass lightly attached on its upper surface to the surface of the diaphragm. The mass was explored number of places with a wide-bore aspirating needle, but pus was located. The abdomen was then closed with givings as to the wisdom of operation. The spleen enlarged and soft. After operation the patient made uninterrupted recovery, and the liver regressed and fin disappeared under the costal margin. Subsequently she seen regularly and six months later was perfectly well.

The patient remembered after operation that at age of 10 she fell over and a pin on the carpet penetra the abdominal wall, but it gave her no trouble and quickly forgot the incident. The histological report the excised portion of the liver stated that the specim consisted of scar tissue with chronic inflammat changes around a central focus consistent with presence of a foreign body.

London, N.11.

R. F. HENDTLASS.

THE FIRST MEDICAL EXAMINATION

SIR,—Dr. Johnson's plea (Sept. 17) "for a mo searching consideration of the nature of the standard of the 1st M.B. examination would have some valid if the medical schools could absorb all who pass examination. My daughter was successful in the Lond external 1st M.B. examination this year but has be unable to obtain a place to continue her studies eith in London or the provinces. She informs me that th are dozens in similar plight.

Truro.

V. E. WHITMAN.

WHY NOT GENERAL PRACTICE?

SIR,—Your leading article of Aug. 27 touches fundamental points. Very little, however, is said abou immediate changes which could be made without adjust ment of the curriculum or new appointments to th staff.

A large number of disorders encountered in gener practice in themselves rarely necessitate admission hospital. Many of these complaints, however, arise patients seen in hospital, and too little is done to brin the notice of students to them. Mild neuroses, bronchit fibrositis, headaches, and mild hallux rigidus and oste arthritis are probably some of the commonest. The must be taken into consideration anyway if the pati is to be treated as a whole.

There are, however, a large number of very importa conditions commonly seen in general practice whic often need hospital treatment. For various reason some of these conditions are gradually being exclude from undergraduate teaching hospitals. Acute abdomin conditions, abortions, severe chronic bronchitis an emphysema, cerebral thrombosis and hæmorrhage, an pneumonia are examples of these complaints.

Medical undergraduate education has two functions academic and vocational. An undergraduate teachin hospital also has two functions: it has to serve the societ in its neighbourhood, and it has to provide means fo medical education.

Cases are being selected to serve this academic function of medical education to the detriment of the vocational From the point of view of the function of a hospital cases are selected too much to suit sectional and individual interests, too little regard being paid to the needs of undergraduate education and even to the prime function of a hospital, which is to serve society.

The changes over the last thirty years have been so gradual that they have not been fully appreciated. There is much truth in the statement that the be places [illegible] students now are the former when a management committee, to avoid publicity, 's to settle a case and looks to the doctor for a ibution towards the cost of settlement. The interests e doctor, however, may demand that the case should ught in open court for the vindication of his good e and reputation. Such conflicts of interest have t occurred in cases where the Service authorities municipal bodies have been involved, and the medical nce societies know how to handle them.

Obituary

J. TYLOR FOX

M.A., M.D. CAMB., D.P.M.

r. Tylor Fox, who died on Sept. 20, aged 64, had ked for over thirty years on epilepsy, and especially the daily life and employment of epileptics. He ntained that the social handicap of this disease is of all proportion to the physical handicap, and that based largely on public misconceptions which can must be removed. He did much to create a more eful and understanding outlook.

member of the Society of Friends, he was the son of R. Hingston Fox, F.R.C.P., biographer of Fothergill. He was sent to the Friends' schools at Ackworth and Bootham and to the City of London School, from which he won a scholarship to Sidney Sussex College, Cambridge. Qualifying from the London Hospital in 1910, he held a house-appointment at Ipswich and then spent several years in general practice in North London. Next, in 1916, he went to Russia as chief medical officer of the Friends War Victims relief expedition to a famine area.

[Elliott & Fry

"His aim," writes J. R., "was to establish on the remote steppe a hospital of as high a standard as circumstances permitted, and he endured with fortitude and his own quiet humour the many modifications of his ideal which conditions demanded. He would not have been so successful with the peasants if he had not won their affection as a man and their respect as clinician. It was not easy to convince them of the value of modern sanitary requirements, and to persuade them that illness was not a visitation of God's displeasure proved even more difficult.

"On his return to England his report on the war morale of the people late in 1917 was received by High Authorities with incredulity, because it did not coincide with those of the diplomats. But events proved that he was right; reports usually are when based on direct observation. He was, besides a clinician of the individual, a good observer of the masses."

In 1918, soon after coming back, Fox visited the Lingfield Epileptic Colony to help in an emergency; and he remained, as medical superintendent, until 1945. Established in Surrey by the Christian Social Service Union as a home for unemployable epileptics, the colony was already taking children, with the help of grants from local authorities. Under Fox's care it grew steadily larger and became fully self-supporting: by the beginning of the late war it had the biggest epileptic school in the country, with about 250 children, and some 200 adults also had their home there. But despite its size, it still contrived to have something of a family atmosphere; and this was due not least to the medical superintendent. He was very conscientious, taking pains to know every patient; and "when Dr. Fox speaks to you," said one of them, "you feel as though you matter." His particular blend of caution, solemnity, and humour, and the knowledge of his solid kindness, pleased the Lingfield population as it had pleased the Russians. He had integrity without either hardness or self-esteem. He was at the same time a wise physician, and also a keen investigator who was always ready to test any promising method of treatment and to put the resources of Lingfield at the disposal of outside workers. His own clinical contributions included papers in our columns on phenobarbitone (1927) and, with Dr. Gwenyron Griffiths, on rhythm in epilepsy (1938). Though the war brought to Lingfield many difficulties, culminating in flying bombs and evacuation, it also saw some valuable advances on the occupational side. "Occupation and interest," said the superintendent, "are direct anticonvulsants."

When diminishing health obliged Fox to retire from Lingfield in 1945, he was glad of the chance to do more in the campaign for the better care of epileptics. Though generally reserved in manner, and sometimes shyly formal even to old friends, he could speak well and write well; and he had something important to say.

"Until the week of his death," writes D. J. W., "he was working for the social and economic improvement in the lives of epileptic people. He was in touch with clinical neurologists, electrophysiologists, and pharmacologists, but his real interest was in the social field and his work was complementary to theirs. Personally, and in such offices as president of the British branch of the International League against Epilepsy, he was influencing public bodies towards enlightenment in the education, employment, and care of epileptics. His paper on the Social Aspects of Epilepsy, published in THE LANCET in 1947, expressed the aims of that work.

"He was most quiet and retiring; he did not often speak at medical meetings, nor did he write much, although he had great experience of the sheltered epileptic. His choice of epilepsy as his main interest in medicine was fortunate, for his qualities matched a great need. A social reformer must have patience, and it is certain that much that Tylor Fox worked for has still to be done. But he has left behind organisations and enthusiasms to continue the work. Those he cared for in his years at Lingfield are only a few of those he will have helped."

His interest in epilepsy, however, was by no means exclusive. His other public work included membership of the London committee of the Lebanon Hospital for Mental Diseases, and for two years he acted as its chairman.

Dr. Fox married, in 1912, Elsie, daughter of the late Edwin Gilbert, and she survives him. He leaves three children; and in his elder son, already a doctor, the family has reached its seventh medical generation.

GEOFFREY COMMELINE WILLIAMS

O.B.E., M.A. OXFD & CAMB., M.R.C.S., D.P.H.

Dr. G. C. Williams, senior administrative medical officer of the Oxford regional hospital board, died on Sept. 21 at the age of 57. Born at Thornbury, Gloucestershire, where his father was in medical practice, he was educated at Clifton College, Caius College, Cambridge, and Bristol Royal Infirmary. After qualifying in 1916 he served overseas as a captain in the R.A.M.C. for two years, and on demobilisation he became assistant medical officer to the Bristol city fever hospital and sanatorium. In 1921 he took the D.P.H. and in the same year he went to Oxford as assistant medical officer of health, later becoming deputy M.O.H., and in 1930 M.O.H.

Already an M.A. of Cambridge, in 1937 he took his M.A. Oxfd by incorporation, becoming a member of Brasenose College. In 1942 he was appointed O.B.E. for his services to public health and to civil defence. Formerly an examiner in public health in the University of Oxford, he was also a past chairman of the Oxford and district public medical service, and a member of the committee of the Nuffield Institute of Social Medicine, and of the council of the medical staff of the United Oxford Hospitals.

W. S. writes: "Men like Billy Williams can ill be spared in these days when so much hinges on a fair and equitable administration of the new health services. A first-class administrator, he always tended to approach problems from the human side rather than from the point of view of regulations and orders. He was perhaps at his best in times of stress, when his calm and equable

Medicine and the Law

Death after Measles Immunisation

An inquest on the deaths of three children, which was adjourned on Sept. 20, was resumed on Sept. 26. These children, all aged 3 years and a few months, died of acute hepatitis some 7 weeks after the intramuscular injection of serum given on July 1 to immunise them against measles. At the request of Dr. Bentley Purchase, the coroner for St. Pancras, Dr. F. E. Camps described the post-mortem findings in two of these three cases. Both showed advanced liver necrosis, the condition being slightly less severe in one child. He had no doubt from the evidence, he said, that the liver damage was due to the transmission of a substance in serum, used in this case for measles immunisation. Virus transmitted in this way cannot be identified until a case of hepatitis occurs. He was satisfied that the syringes were not responsible; several were used, and a large number of children were immunised on the same day. The syringes were changed after every fourth child, and a new needle was used for each child. It seems that the four children who developed hepatitis (one is still ill) were not injected in succession but were scattered through the whole group treated; it is therefore improbable that the same syringe was used for each of them. It is very unlikely, Dr. Camps said, that the virus would be transmitted by a syringe used for intramuscular injections; contamination is usually the result of intravenous injections, in which a little blood is drawn back into the barrel before the injection is made. The four children infected, with one other child who has not developed jaundice, all received serum from a single batch, only a small quantity of which was used. At the previous hearing, Dr. R. A. Zeitlin, director of the Tottenham blood-transfusion department, said that of the sixty donors who had contributed blood to this batch of serum, five had had jaundice in the past, but all many years ago, well beyond the period within which it was thought to be dangerous.

Dr. Alfred Piney said that pathological examination confirmed that there was severe necrosis of the liver, of the type which occurs with virus infections.

The coroner, summing up, recalled that the three children who died had, with many others, been given the injections at a day nursery, because they were thought to be measles contacts. This method of immunisation is well established, not new, and one local authority has practised it for years without the appearance of any such cases. Of the sixteen children immunised that morning, the five who had the same batch of serum were scattered through the group. Three died and one was ill. Hepatitis shows itself within 60–100 days. It was no fault of the method, he said, that three children died: the danger of infection by hepatitis virus through a serum injection is no greater when the serum is given to protect against measles than when it is given for some other reason. He was satisfied by the evidence of Dr. J. Harrington, who gave the injections, and Dr. Zeitlin, who has charge of the laboratory where the serum is collected, that there had been no sort of neglect or lack of care. The experience gained from these unfortunate cases might be of practical use in serum immunisation, in the future, but that was not the province of his court. He was satisfied that the deaths were due to injections of serum given in July, and he brought them in as deaths by misadventure.

The Wrong Cylinder

In Dublin District Court last week, the judge rejected the prosecution's case against a house-surgeon charged with having unlawfully killed a patient who died while under an anæsthetic.

At earlier hearings and in a previous statement the house-surgeon had testified that on May 30 she decided
to administer nitrous oxide and oxygen to an outp
for the purpose of operating on a septic thumb.
the house-surgeon, noticed that the oxygen c
on the apparatus was empty, and she asked a n
get a full cylinder; she did not check the c
brought by the nurse but tightened it up and tur
the nitrous oxide fully and the oxygen partly
noticed that the patient was becoming cya
and she then turned the nitrous oxide off and the
fully on. The patient became still more cya
and it was found that both cylinders contained
oxide. Oxygen was administered from a fresh
two intracardiac injections were given, and a
respiration was begun and was continued for som
without success. In cross-examination the
surgeon said that she knew that one or other
nitrous oxide or oxygen cylinders had a white t
she did not know which.

For the firm supplying the cylinders it was stat

Legal Proceedings in the N.H.S.

A memorandum lately circulated to boar
management committees *indicates that the*
Health is anxious to be kept out of legal p
against hospitals. The proper course for a
solicitor is to institute proceedings against the
ment committee or the board of governors.
appropriate, the management committee shoul
assistance from the solicitor of the regional
board. The Ministry should be consulted in cases
ing the construction of the Act and the regulat
cases where an application is being threatened f
to apply for a writ of mandamus, and in cases in
legal questions of first-class importance.

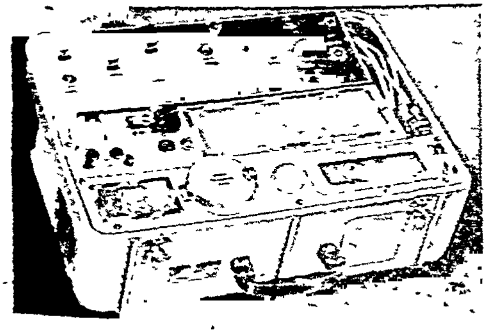
Where a claim is based on negligent treatme
nurse, it is to be expected that the claim will be
her employer, and the nurse will not be made a
defendant. *If, however,* the nurse is joined
proceedings, the employer is authorised to see
defence if she so desires, and in such cases the
acting for the employer would normally act
defendant nurse as well. Where, on the other ha
nurse has acted quite outside the scope of her au
the Ministry holds that she ought to be left to
her own defence. Though it is stated that suc
should be referred to the *Ministry for consid*
nothing is said about whether a nurse conduct
own defence would also be expected to pay for
looks as though she would. If so, nurses may wel
that the time has now come when they should
defence organisation like those that have p
members of the medical and dental professions fo

The memorandum points out that, generally sp
"authorities are not authorised to undertake the
of hospital doctors who may be sued in respect of
negligence,"; if it is sought to make an authorit
for negligent acts of a doctor, it should normal
such steps as are open to it under the Law
(Married Women and Tortfeasors) Act, 1935, *to*
a contribution from the doctor in respect of d
that may be recovered. This makes it clearer th
that every doctor and dentist should *have* m
providing for their own defence. There may well b

s now termed—who took charge of treatment might also nder the medical officer of health in connexion with reventive aspect. The major difficulty now facing the culosis service was to ensure coöperation between the 1 officers and the hospital service; the hospital clinician tend to look at the patient in the hospital bed but to n, as it were, unconscious of the dire needs of the patient le. The tuberculosis officer now had more fully at his sal the resources of the hospital service; and he still ned the head of the tuberculosis service, under the istrative control of the medical officer of health for ions other than actual treatment. One or two local rities were failing to pull their weight; a few seemed ve adopted the mistaken attitude that the bulk of the had passed to the regional board and that they need ery little. Some might be tempted to have a cynical d for the word "coöperation"; but the administrative ture must be assumed to have some permanence, and on sense freely dictated that the various services must together. In all this the health officer and his invaluable the health visitor, had, as in all diseases of social rtance, a major part to play.

DIRECT-RECORDING ELECTROCARDIOGRAPH

NEW electrocardiograph, marketed as model 1314 by rs. A. C. Cossor Ltd., incorporates an electronic amplifier, h, in combination with an inkless two-speed recording provides a direct permanent record by the passage of lectric current through sensitised paper. The normal tivity of the instrument is 1 cm. per millivolt, which is generally accepted standard. One 150-ft. roll of calibrated rding paper is sufficient for 30 minutes' continuous running ld occasion demand. The instrument is completely mains-en and is stabilised against reasonable line voltage fluc-ions. Either of the two recording speeds of 2½ cm. per and 10 cm. per sec. can be selected during a recording a switch-operated automatic gear-change mechanism. nexion to the patient is by a plastic-coated, four-core, ened cable, which separates into four individually marked l coloured leads with pin connectors to the sprung contacts stainless-steel electrodes. The chest electrode, which can detached for cleaning, is operated by a pressure bulb, and tact is maintained pneumatically. For adjustment of the n, a lens is fitted into the window above the recording ms. A multiple switch is incorporated to give standard ds 1, 2, and 3, the C.R. lead, and the "Wilson indifferent trode" as well as augmented unipolar tracings. In its the instrument weighs about 50 lb. and is no larger than mall suitcase.



Dr. T. S. Stone writes: "This electrocardiograph has been use at the Ramsgate and Margate General Hospital for three nths and has proved very satisfactory. We have direct-rent mains here, so a small converter has to be used and s gives excellent results with no interference. Equally good ults are obtained in parts of the town supplied by alter-ing current provided that the mains supply is adequately rthed. The machine is really portable and seems able to thstand a reasonable amount of rough handling. The method f direct recording makes it possible to give an opinion immedi-tely at the patient's bedside; moreover, a continuous tracing an be taken almost indefinitely—a valuable aid in disorders f rhythm. The switch that increases the motor speed four times, and so gives the effect of a slow-motion record, has also proved useful in cases of tachycardia. The apparatus is easy to use. The one-knob control that enables standard, chest, polar chest, and augmented limb leads to be obtained by pressing a button is simplicity itself."

DISTRIBUTION OF GENERAL PRACTITIONERS

THE following further amendments have been made to the Medical Practices Committee's classification of executive-council areas described in our issue of July 30 (p. 211). The first list of amendments was published in our issue of Aug. 20 (p. 355). Schedule 1 contains the names of parts where more doctors are needed; Schedule 4 of the "closed areas."

Schedule 1

CORRECTION

Glamorganshire.—Neath should read Neath Municipal Borough.

Schedule 4

ADDITIONS

Carmarthenshire.—Pontyates, Trimsaran.
Glamorganshire.—Dinas Powis, Radyr.
Cumberland.—Silloth.
Devon and Exeter.—Roborough, Sampford Peverell, Bere Alston, Chagford, Hemyock, Ipplepen, Torrington (Great), Whimple, Lewdown.

DELETION

Devon and Exeter.—Chudleigh.

STREPTOMYCIN SUPPLIES

HITHERTO the use of streptomycin in Great Britain has been mostly limited to controlled studies. Owing to increased production, from Nov. 1 it will be generally available on prescription. Announcing this, the Ministry of Health states that the only continuing administrative controls over this antibiotic will be those imposed by the Therapeutic Substances Act, and by the Penicillin Act which makes its procurement subject to medical prescription. The Ministry urges that streptomycin should be used "only in conditions, or to combat infections, in which its efficacy is known . . . the proper place for the experimental trial of this antibiotic in unusual conditions is the hospital, not the home." Its two main disadvantages are: (1) toxic effects, which may be permanent; and (2) the evolution during treatment of strains of the infecting organisms which have developed a resistance to streptomycin. Adequate doses should be given from the start, and sometimes it may be preferable to give larger doses than usual for up to one week, since serious toxic effects do not appear to develop within that period. "In any case, if the expected therapeutic response is not obtained in that time, reconsideration of the treatment is indicated." The Ministry statement denies that the substitution of dihydro-streptomycin for streptomycin itself would reduce the risk of toxic sequelæ.

PUFFING AND BLOWING

THE child-health and medical illustration departments of Guy's Hospital have published a four-page card of "Special Breathing Exercises for Children," in which simple devices for expanding the lungs—blowing a ping-pong ball, keeping a feather in the air, blowing soap-bubbles, and distending a balloon—are described and illustrated. The intention is that children with chest complaints should keep the card on the mantelpiece at home and do the exercises there. It is a good idea and the card is quite nicely done; but with a little more thought it could have been done even better. Children old enough to read the directions for themselves will think some of the pictures rather babyish; they will also be puzzled to come across the word "abdomen" in the otherwise simple text. Moreover, one may doubt whether the title of the card, which appears in large letters at the top of the first page, will win the coöperation of a young person who is already bothered by his breathing and feeling out of things because of it. Anyone who was required to do "special exercises" for anything in childhood will recall how humiliating it was. But the principle is thoroughly sound, and this is only a first edition of the cards: later editions will no doubt improve on it. Meanwhile this is a useful beginning, and those needing the cards for distribution can get them from the hospital at a cost of 9*d*. each, 33*s*. for 50, £3 for 100, and £25 for 1000.

CARDS FOR A GOOD CAUSE

THERE is a story in the Grenfell family that Sir Wilfred once met a lady on a boat, and after a week's acquaintance asked her to marry him. "But you don't even know my name!" she exclaimed in surprise. "What does that matter?" he demanded; "it'll soon be the same as mine"; and so it was. In the same spirit of happy confidence he carried through his work in Labrador. The fishermen who lived there in isolated hardship must have doctors, nurses, and hospitals he decided; and soon they had the Grenfell Mission extending along a thousand-mile coastline, ice-bound character shone forth conspicuously. His discreet and tactful intervention at committee meetings many times smoothed out what might have developed into an awkward situation. His motto could well have been Service before Self, and even his intimate friends did not always know how much help he gave to those in trouble.

"Williams was a man of the highest integrity and all with whom he came into contact soon recognised this quality. While M.O.H. for Oxford his relations with the general practitioners were particularly happy. He had few hobbies, but until he became absorbed in civil defence duties he enjoyed a round of golf.

"He spent the last days of his life in the Slade Hospital, a modern institution for infectious diseases, for the construction and planning of which he was largely responsible."

Dr. Williams married, in 1919, Irene Mary Durant, who survives him with one daughter.

HARRY SMITH

M.R.C.S., D.P.H.

Dr. Harry Smith, who died on Sept. 16 at the age of 48, was one of the nine divisional medical officers appointed to administer the local-health-authority services of the London County Council.

After taking the Conjoint qualification from St. Bartholomew's Hospital in 1924, he held resident appointments in hospitals in Rugby and London, and worked in general practice from 1926 to 1931. He looked back on these five years, spent in rural practices in the West of England, with particular affection, and he used to say that the intimacy of the personal contacts lent general practice a quality unattainable in other branches of the profession.

For two years he was an assistant school medical officer at Plymouth, and from 1934 assistant M.O.H. at Portsmouth. His experiences in these provincial appointments were part of the equipment which made him so valuable when he joined the London service in 1938. His first work in London was in the slum-clearance programme which before the war was a large and important part of the health department's functions. During the war he undertook varied duties connected with the school health service, the medical examination of staff, and first-aid training. He was promoted to divisional medical officer in 1941 and principal assistant medical officer in 1946.

Dr. Smith took up his post as divisional medical officer in April of last year, and his charge included Chelsea, Fulham, Hammersmith, and Kensington. A colleague writes, "His energy, his skill in health administration, and his ability to get on with all kinds of men, women, and, above all, children eased the process of establishing the new structure. His wide knowledge of the law and practice of public health and his ready adaptability to new circumstances quickly gave him a high reputation among his colleagues, the members of the divisional health committee, and the wide section of the population with whom he came into contact."

Appointments

BUTTLE, R. L., M.R.C.S., D.P.M.: psychiatrist, Fulbourn Mental Hospital, Cambs.

CHRISTIE, A. L. M., M.B., PH.D. Lond., M.SC. N.Z.: second pathologist, Norfolk and Norwich Hospital.

CLARK, G. M., M.B. Glasg., D.P.H.: temporary tuberculosis physician, Glasgow northern hospitals.

MOORE, B. P. L., M.B. Belf.: provincial medical director, British Columbia depot, Canadian Red Cross Blood Transfusion Service.

STEWART, C. J., M.D. Lond., D.OBST. R.C.O.G.: chest physician, Ipswich and East Suffolk area.

Colonial Service:

EVANS, W. J. M., M.B. Lond.: senior M.O., Tanganyika.
HARRIS, F. C., M.R.C.S.: M.O., Gold Coast.
JOHNSON, A. J., M.B. Camb., D.T.M. & H.: senior M.O., Sierra Leone.
LOW, K. N. H., M.R.C.S.: M.O., British Guiana.
MURCOTT, E. H., M.B. Edin., D.P.H.: senior M.O., Kenya.
NUGENT, D. A. W., M.B. Madras: M.O., Gold Coast.
WILKINS, VIOLET, M.B. Edin.: lady M.O., Nigeria.
WINGATE, M. B., M.R.C.S.: M.O., Northern Rhodesia.

Notes and News

EMERGENCY BED SERVICE BRANCHES OUT

DURING last winter applications for the admission of pat were received from doctors and hospitals at a greater than could be immediately dealt with by the office of service at Old Jewry, which was responsible for the whole Greater London. Some accumulation of less urgent ca was inevitable, which caused delays in informing doctors the disposal of their cases and undue strain on the To avoid these delays during the approaching winter, w the approval of the four Metropolitan regional hospital boar branch offices of the service are being opened to deal with outer part of Greater London. The following offices (wi the exception of the south-western branch at Wimbled will open on Oct. 3, and will accept cases from general prac tioners and hospitals in their area from 8.30 A.M. until 9 daily (including Sundays). They will be closely linked w other branches and with the central office at Old Jew During the night a full service for the whole of Greater Lond will be available at the central office.

CENTRAL OFFICE: 10, Old Jewry, E.C.2. (MONarch Covering by day Central London only (i.e., the area not cove by the four branch offices); by night (9 P.M.–8.30 A.M.) the wh of Greater London.

WESTERN BRANCH: 81, Mattock Lane, Ealing, W.13. (EAL 6671.) Covering Acton, Ealing, Hounslow, Staines, Uxbrid Harefield, Northwood, Pinner, Harrow, Stanmore, Edgware, Hill, Hendon, Willesden, Wembley, Brentford, and Twickenham.

The E.B.S. is a purely auxiliary service intended to sa the general practitioner's time, and doctors will of course direct to the hospital if they wish, except for cases of infectio diseases within the County of London. The E.B.S. d not deal with mental cases or with tuberculous cases ot than acute emergencies. The availability of beds during coming winter depends on factors outside the control of E.B.S., but with the help of the new offices it is hoped answer doctors' applications more rapidly than last y Doctors will help by ringing the office nearest the pati home; the full resources of the E.B.S. will be availa through any of its offices.

TUBERCULOSIS IN SCOTLAND

SPEAKING in Edinburgh on Sept. 20, Sir Andrew David chief medical officer of the Department of Health for Scotla observed that tuberculosis remained the black spot Scotland's health record. Scottish experience differed fr that of many neighbouring and similar countries, for favourable pre-war trend, which had been seriously interrupt by war-time influences, had not been resumed as it had el where. The round figures for Scotland were: about 30, cases on the tuberculosis registers; 8000 new notificatio during 1948, when there were 3400 deaths; some 2 patients awaiting admission to hospital; and nearly 5 beds for treatment and isolation, of which nearly 600 w empty and unstaffed. Nevertheless, knowledge justif people thinking in terms of complete control and ev eradication. Already the increase in new cases notif through improved case-finding was proportionately grea than the increase in deaths.

The primary responsibility for the patient at home m rest with the general practitioner; with the need for ca segregation and treatment, the family doctor had in tub culosis a function which was perhaps more important than in a other disease. On the hospital side a double integration w needed: the regional board must be integrated first w the general medical services of the area, and secondly with t epidemiological, social, and environmental aspects of t work. Thus regional boards had been advised that d appointments might in certain circumstances be of permane advantage; the tuberculosis officer—or chest consultant

ACUTE MASTITIS

ANTHONY WALSH
M.B. Dubl., F.R.C.S.I.
CAL REGISTRAR, ROYAL SOUTHERN HOSPITAL, LIVERPOOL

TE mastitis is an all too common disease which ot had the attention it deserves. Fulton (1945) in dy of puerperal and lactational mastitis in a town ,000 inhabitants found an incidence of nearly 9% deliveries. Breast infection is rarely fatal and n the cause of serious illness, but it is undoubtedly ise of considerable maternal morbidity following irth. The comparative neglect of the subject is n by the fact that from 1940 to 1947 only eight papers is theme were listed in the *Quarterly Cumulative*

the past treatment has been unsatisfactory. Most progressed to abscess formation; indeed many encouraged to do so. When the abscess was judged "ripe" the standard radial incision was made, s were ruthlessly torn to make certain of draining culi, and large rubber tubes were placed in the ting cavity. Often it was a matter of weeks before was final healing, and always there was the fear recurrence; so an infected breast was a calamity he patient and a nuisance to her doctor, not to ion the potential ill to the infant of weaning too . Though, in good hands, the end-result was usually actory, far too often the combination of the disease its treatment left a maimed organ and an ugly

is paper is based on the study of 153 cases of acute itis treated in the wards of Smithdown Road ital, Liverpool, between December, 1945, and ary, 1947. My object was to discover the best s of treating the disease, with the following parti- aims in view: (*a*) rapid control and cure; (*b*) mini- interference with breast-feeding; and (*c*) minimal ing in cases requiring drainage.

ÆTIOLOGY

l but 1 of the 153 patients were lactating or pregnant en. The single exception was a virgin aged 19 with all abscess in the breast for which no cause was d. The relation to parturition of the remaining 152 s is shown in table I.

om this table it will be seen that although there more cases in the second puerperal week than ny others, a considerable number occurred later. aps the most noteworthy point is that over half found at a time when the patient would not nally be in hospital; hence the responsibility for diagnosis and treatment rests with the general titioner.

BLE I—TIME OF ONSET IN RELATION TO PARTURITION

has long been recognised that the principal bacterial t in acute mastitis is the *Staphylococcus aureus*. This been confirmed in the present series. Pus was obtained 7 cases, and 51 of them yielded a pure culture of ulase-positive penicillin-sensitive *Staph. aureus*. In tion, 5 of the 57 grew hæmolytic streptococci. In the aining case a pure culture of hæmolytic streptococci was obtained: in this patient there was a considerable abrasion at the base of the nipple and swabs from the throat gave a growth of streptococci of the same type (Lancefield group A). In the 5 cases in which both staphylococci and streptococci were found the streptococcus appeared to be a secondary invader; in all of this group a long incision had been made for drainage, and initial cultures showed only staphylococci. The importance of preventing secondary streptococcal invasion will be emphasised later.

I have made no attempt to evaluate the various ætiological factors involved. Nevertheless, I have been struck most forcibly by the significance of milk stagnation. Borrowing the jargon of the mathematician, I would term milk stagnation the "highest common factor." A well-known predisposing cause of acute mastitis is cracked nipple, which was observed in 31 cases of the present series. In most of these 31 the initial lesion appeared to be a reticular lymphangitis of the subcutaneous tissues with secondary spread to the mammary parenchyma. In the remaining 121 the infection seemed to have entered along the ducts (although blood-borne infection cannot be discounted).

There are three chief ways in which acute mastitis may be established:

(1) Retrograde infection along the ducts to a zone of stagnant milk behind some block. This is analogous to the infection which so commonly follows chronic retention of urine; but milk is far superior to urine as a culture medium for the pathogenic cocci.

(2) Reticular lymphangitis spreading in the subcutaneous tissues from a cracked nipple. The inflammatory reaction causes compression of the nearby ducts with resultant milk stasis. The "pool" of milk is rapidly invaded by the adjacent organisms.

(3) Blood-borne infection of a milk-retention "cyst."

Here we see perhaps the chief reason why acute mastitis is so common in the first two weeks of lactation. Before the flow has been properly established there is a greater likelihood of obstruction by epithelial debris than later when the ducts are kept clear by the frequent passage of fluid. Reference to table I shows that the incidence of acute mastitis does in fact diminish as the duration of lactation increases. Breast infections occurring in later months are most often found when lactation is ceasing, or rather during weaning when the emptying of the breast may not be complete and some residual milk lies in the ducts. (Though a huge abscess was seen in one patient in this series who had been suckling her child for eighteen months and had apparently not even begun to consider weaning.) Again, it is common in a patient with a breast abscess, apparently well on the road to recovery, to see a second or third abscess appear in a part of the breast remote from the original infection, often in the axillary tail. Such secondary abscesses are usually due to the milk retention which is so likely in a breast which cannot easily be emptied completely.

If this hypothesis is correct, then it must be of paramount importance in the treatment of acute mastitis to ensure that the breast is properly emptied of milk, and kept empty. This is abundantly borne out in the present series. Altogether there were 57 cases of abscess formation. In 12 of these, treatment was by simple incision and systemic penicillin, with no special care to avoid milk retention, though in all 12 the child was weaned and stilbœstrol was administered to inhibit lactation: of these 12, 3 developed a second abscess in the axillary tail. In the remaining 45 cases great care was taken to prevent the retention of milk, and lactation was encouraged rather than inhibited. In none of these 45 (all treated by drainage and the same dosage of penicillin) did a secondary abscess develop.

for many months in the year. Now, after more than fifty years of splendid service in this harrowing climate, the hospitals badly need rebuilding and enlarging, equipment needs replacing, and surgical and medical supplies must be maintained.

One way to help with this work is to join the Grenfell Association; subscribers of 10s. a year become associate members and receive the quarterly journal. Another way is to buy Christmas cards from the association. This year there is, in addition to some old favourites, an attractive new card, by Rhoda Dawson, of two Labrador housewives on their way to church, their hands tucked into the sleeves of their white fur sweaters, and their little black-and-white moccasins barely showing under their blue print dresses. A winter scene by Stephen Hamilton also has charm; and a group of husky puppies photographed on a sledge are as confident of approval as the baby pandas they resemble. Seascapes by Cecil S. Ashdown may also be bought, as postcards; and the association runs a stamp bureau for philatelists.

Orders for Christmas cards should go to the secretary of the Grenfell Association, 66, Victoria Street, London, S.W.1; requests for stamps to Mrs. Mackay, 88, Exeter House, Putney Heath, S.W.15.

University of Leeds

The inaugural lecture of the faculty of medicine will be given in the Riley-Smith hall of the University Union on Friday, Oct. 7, at 3 P.M., by Prof. John Cruickshank, who will speak on Medicine Today and Tomorrow.

Royal Medico-Psychological Association

This association's Maudsley lecture will be delivered on Thursday, Nov. 3, at 2.15 P.M., at 1, Wimpole Street, London, W.1, by Mr. W. Grey Walter, SC.D. He is to speak on the Functions of Electrical Rhythms in the Brain.

Faculty of Homœopathy

The presidential address will be delivered at the Royal London Homœopathic Hospital on Thursday, Oct. 6, at 5 P.M., by Dr. Margery G. Blackie, who will speak on the Place of Homœopathy in Modern Medicine.

Hammersmith, West London, and St. Mark's Hospitals

Prof. Ian Aird has been appointed to the board of governors of this group of teaching hospitals in succession to Prof. J. H. Dible.

York Medical Society

The new session of this society will open on Oct. 12, when Sir Henry Cohen, this year's orator, will speak on New Pathways in Medicine.

Vellore Christian Medical College

The annual reception and conference of the Friends of Vellore is to be held at the Alliance Hall, Palmer Street, London, S.W.1, on Thursday, Oct. 6, at 3 P.M.

Adlerian Society of Great Britain

The first meeting of this society's medical section is to be held at 11, Chandos Street, London, W.1, on Thursday, Oct 13, at 8 P.M., when Dr. Neville Murray and Dr. Joshua Bierer will discuss Prolonged Sneezing as a Psychosomatic Symptom.

Chiropody in Scotland

Addressing the Society of Chiropodists in Edinburgh on Sept. 22, Sir George Henderson, secretary of the Department of Health for Scotland, said that his Department hoped to develop a chiropody service in association with health centres; and the Department's first experimental centre—at Sighthill, Edinburgh—would include a room specially earmarked for this purpose. The Department was also considering methods by which a chiropody service could be developed in connexion with groups of general practitioners, in advance of the building of health centres.

Interdepartmental Committee on Registration of Opticians

The Minister of Health and the Secretary of State for Scotland have appointed a committee, under the chairmanship of Lord Crook, to advise, on the assumption that statutory registration of opticians would be to the public interest, how such registration could best be achieved and what qualifications should be required. The medical members of the committee are Mr. G. W. Black, Dr. Macdonald Critchley, Prof. C. A. Lovatt Evans, F.R.S., Mr. John Marshall, and Mr. O. Gayer Morgan.

Manufacture of Thyroxine

The manufacture of *l*-thyroxine on a commercial scale h been achieved by the research division of Glaxo laboratories

Manufacture of Cortisone

B.U.P. reports that at least five American companies trying to synthesise 'Cortisone' are to exchange patents.

Weekend Courses on Rheumatic Diseases

A course is being held at the rheumatism unit of St. Hospital, Fulham Road, London, S.W.10, on Oct. 1 and 2

A course arranged by the Empire Rheumatism Council be held in London on Nov. 18–20. Further information be had from the general secretary of the council, Tavi House North, Tavistock Square, London, W.C.1.

Cinemicrographic Film Library

The Royal Microscopical Society has established a ci micrographic film library for the benefit of univer technical schools, and other scientific bodies. Inqu should be addressed to the assistant secretary of the soc B.M.A. House, Tavistock Square, London, W.C.1.

Prof. J. C. Spence left on Monday for Czechoslova where he is spending two weeks lecturing for the Bri Council.

classical picture of the mature infection. The onset e obvious, with a rigor, pyrexia, pain and tender- the breast. This, however, is by no means the nd it may be very difficult in an early case to ntiate between an infection and the "flushing" milk engorgement which is commonly seen in the eek of lactation. Where the diagnosis is in doubt, tient should be regarded as having acute mastitis : r better that occasionally a mother should have a nnecessary injections than that an infection be time to establish itself before active therapy is This attitude is comparable to the giving of phtheritic serum on the *suspicion* of diphtheria. icillin *is administered early enough in every case,* s formation should never occur.

st observation from this series repeats what has been said in earlier writings. I refer to the value quate support to the inflamed organ so that it is irmly and comfortably slung as high as possible. s undoubtedly a factor of importance in treat- and adds considerably to the comfort of the it.

illary methods of treatment—e.g., with short-wave rmy and X rays—have not been used in this

REATMENT WHEN AN ABSCESS HAS FORMED

peatedly in the vast literature on penicillin we find sistent theme that the use of penicillin is no sub- e for surgery. It has been shown, for example, n the treatment of the septic finger penicillin may resolution if no pus has formed, but once suppura- as set in, the sooner the infective focus is drained oner will the lesion be cured. The same principle true in the treatment of a breast abscess. As soon s has begun to form in the mammary tissue no should be lost in evacuating it. Since the advent sulphonamides and the antibiotics it has been the ice of many people to ply the patient with these until the abscess has "localised," and to wait ps many days before instituting drainage. Such a ice may be harmless enough in a patient with a taneous abscess but it cannot be too strongly mned where there is pus in the breast tissue. astination in the treatment of a mammary abscess esult only in damage, perhaps irreparable, to more nore of the parenchyma.

e need not see many such cases to learn that it is more difficult to obtain a rapid cure when an s involves only part of the breast than when the organ has become a bag of pus. In the latter simple drainage usually suffices without any otherapeutic or antibiotic aid; the condition is ly relieved, though of course the patient has suffered amounts to a functional mastectomy. Why is an s less responsive if there remains any sound breast e? To pose the problem another way: how does a t abscess differ from any other abscess in a relatively icial site? The answer is not far to seek. When bscess is formed, neighbouring ducts tend to become ucted either by the inflammatory process or by lial debris. Such obstruction is followed by the lopment of a milk retention cyst. These lactoceles may be found in many breasts when opening an abscess. Sometimes they are little more than slightly distended ducts, but quite often they are appreciably larger and they may be an inch or more in diameter. These enclosed repositories of stagnant milk are extremely susceptible to infection by direct spread from the nearby focus. The longer an abscess is present and the larger it grows, the more ducts will be blocked, the more "milk cysts" will be formed, and the greater will be the opportunity for invasion of new areas by the offending staphylococcus. If the infection progresses until the entire gland is destroyed, the lesion now differs in no way from any other simple subcutaneous abscess and it responds rapidly to simple drainage.

If early drainage is so imperative, it is important to recognise the early signs of pus formation in an infected breast. *This may not be easy.* In hospital practice the patient is usually not seen until the abscess is obvious; but now and then one encounters the woman in whose breast there is an inflamed indurated zone in which no fluctuation or other definite evidence of pus can be detected. In such cases one should not wait for the appearance of fluctuation; for the abscess has often reached a considerable size before fluctuation is evident, depending to some extent on its depth. Any area of tense induration in an inflamed breast should be regarded as containing pus and drained accordingly. It is in just these cases, with an area of induration rather than a frank abscess, that pain is greatest; and the relief afforded by incision is immediate and should not be denied to the patient. It is not uncommon to meet with cases of mastitis which have been lingering on for weeks under insufficiently vigorous treatment and in which there is a zone of induration which is only moderately tender. These cases seem to be progressing neither to suppuration nor to resolution; the forces of invasion and defence are in a state of uneasy truce. In such patients it is justifiable to observe for a few days the effect of systemic penicillin in a dosage of the order of 50,000 or 100,000 units every four hours. In a few instances a considerable improvement will take place and one may persevere with conservative therapy; but if the zone of thickening is not appreciably less by the third day the breast should then be incised.

In this series 9 patients were seen with a sharply limited sector of inflammation in which could be felt an acutely tender zone of induration. Pyrexia varied from 99·8 to 102·4°F. In the first 4 of these cases I had not realised the necessity for immediate incision, and they were treated with systemic penicillin—50,000 units four-hourly. Within twenty-four hours the temperature had returned to normal and the local signs were appreciably less severe; but after the initial improvement the condition became static and at the end of five days the indurated area was no less. Of these 4 patients 2 were kept on penicillin for eight days and then discharged, but in each some thickening was still present three months later. The other 2 had an incision made into the indurated area on the fifth day: in both, pus was found and resolution was thereafter fairly rapid. The remaining 5 breasts in this category were incised on the first day of treatment and also given the same penicillin dosage of 50,000 units every four hours. All 5 patients were discharged on the fourth day and when seen a week later were cleanly healed with no residual thickening.

Many patients had been treated at home, with sulphonamides or penicillin or both, and were sent to hospital with a note to the effect that "the condition has now localised and is ripe for incision." Alas, the great majority of these were over-ripe. True, many had only a small superficial abscess, but nearly always this proved to be of the "collar-stud" type leading through a

TREATMENT OF SIMPLE ACUTE MASTITIS WITHOUT ABSCESS FORMATION

The series contains 96 cases of simple acute mastitis without abscess. In all of them, as soon as the diagnosis was made, a course of systemic penicillin was begun, the routine dosage being 20,000 units intramuscularly every four hours, continued until the inflammation had completely resolved.

In the first 8, all occurring in the first puerperal week, the infant was weaned and lactation suppressed by the usual methods, including administration of hexœstrol and limitation of fluids. Of the 8 cases, 5 improved rapidly and were considered cured after ten penicillin injections: in all 5 lactation was speedily suppressed. The other 3 are of greater interest as in them the breasts became engorged with milk and had to be emptied with a pump. Though treatment of these 3 was begun at the first sign of inflammation, the response was not nearly so rapid as in the 5 cases where lactation ceased quickly. 2 of the 3 required twenty-five injections before resolution was complete. The 3rd case developed an indurated area in the axillary tail: this did not appear to suppurate but forty injections of penicillin were required before the breast became normal. I suggest that the poorer response in these 3 cases was due principally, if not entirely, to failure to achieve complete emptying with the breast-pump. This thesis is more fully elaborated below.

The criticism may be made that the dosage of penicillin was rather low, and it may be suggested that the 3 patients in whom resolution was delayed would have done better with a larger dosage. This criticism is possibly valid, but it does seem significant that the delayed resolution was in those patients in whom the infected breast became greatly engorged.

The relatively low penicillin dosage has been unexpectedly vindicated in the recent exposition by Eagle and Musselman of the therapeutic importance of the "zone phenomenon." Maximum bactericidal effect on the *Staph. aureus* is achieved by a concentration of about 0·1 unit per ml., and no increase beyond this quite low concentration will accelerate the bactericidal effect. (Since completing this series, I have employed 100,000 *units intramuscularly every four hours as the routine* dosage, for some strains of *Staph. aureus* are relatively less sensitive to penicillin.)

In the remaining 88 cases the same penicillin dosage was used (20,000 units four-hourly), but instead of suppressing lactation the milk flow was encouraged. Feeding from the uninvolved breast was continued in unilateral disease and the infected breast was emptied after each feed. This emptying was accomplished by the patient herself by manual expression. Manual expression was preferred to the use of the breast-pump as a better means of achieving *complete* evacuation. If suction is applied to a tube obstructed at any point the suction will not empty the tube beyond the block but merely cause collapse of the tube between the block and the sucker. (Unless of course the tube is rigid or otherwise resistant to external pressure.)

Pain or tenderness did not interfere to any significant extent with the manual expression of the milk; for one of the most striking effects of penicillin therapy was the rapid relief of pain. The patient was taught to empty the breast as completely as possible, special attention being paid to the axillary tail. As soon as all clinical signs of infection had disappeared, normal feeding was resumed. A major advantage of this procedure is that there is minimal interference with the infant's diet and weaning is unnecessary. The importance of this is obvious and should not need to be stressed.

What danger to the child arises if breast-feeding is continued? All the standard textbooks recommend weaning, and heretofore this practice has generally followed, although Florey et al. (1946) and T Way (1946) have advocated continued breast Before recommending such a fundamental tactical one must be satisfied that no harm will result and in fact considerable advantage will be gained. advantage to the mother has already been shown continued lactation with proper emptying of the makes for easier and more rapid control of the Possible advantages to the child in the breast-feeding where possible are well recognised need no further emphasis here. It remains to be sidered whether or not there are any dangers in a mother to feed her child while carrying in her breast. At first sight one would run a considerable risk of giving the child a enteritis.

Altogether in this series 74 women with simple uni acute mastitis continued to feed their child from healthy breast, and these feeds were supplemented milk expressed from the inflamed breast and boiled five minutes before being given to the baby. 10 wo had bilateral acute mastitis and in all 10 the baby fed on the boiled expressed milk. In these 84 cases child developed a gastro-enteritis. (1 had green st for twelve hours.) This happy result was secured des a minor epidemic of diarrhœa and vomiting in maternity unit during the period under review. Tay and Way (1946) allowed the infant to feed dir from the infected breast and reported that no baby their series developed gastro-enteritis. I would hesitat support this practice, preferring to boil the milk f rather than allow direct feeding.

In 25 cases culture of the milk from the infected bre was made. In 24 of these a mixed growth was obta of *Staph. aureus* and *Staph. albus*. In the 25th c *Staph. albus* was grown. In all 25 cases the milk was ste on culture after five minutes' boiling. As a con cultures were made of the milk of 25 apparently hea mothers. Only 1 of these mothers yielded milk w was completely sterile—in all the remaining 24 St *albus* was grown and in 4 of these *Staph. aureus* as w In all the 25 control cases swabs from the nipple gr the same organism as the milk in the correspond case, and the 4 mothers who showed *Staph. au* had an apparently identical *Staph. aureus* in th nostrils.

This series is admittedly small, but the facts c suggest that there is no danger to the child in the co tinuance of breast-feeding in the presence of ac mastitis, provided the milk from the infected breas boiled for five minutes before being given to th baby.

In 4 of the 88 cases, the baby was dead at the time o the onset of the infection, and so it was obvious desirable to suppress lactation. The same principle o achieving complete emptying was nevertheless applied The breasts were emptied by manual expression thr times daily until all lactation had ceased; once eac day the emptying was done by the ward sister or th house-surgeon to ensure that all areas, particularly th axillary tail, were thoroughly evacuated.

The next point to be stressed is the urgency of beginni penicillin therapy as soon as there is any suspicion of th onset of acute mastitis.

Table II bears out the contention of so many writers that in diseases amenable to the action of penicillin th sooner active treatment is begun the easier it is to control the infection. It is obvious from this table that a delay of as little as twelve hours in commencing treatment may add greatly to the inconvenience suffered by the patient. If we are to brook no delay we must be watchful for the *early* signs of the onset of mastitis and not merely a small tenotomy incision over the point of m swelling.

CONCLUSIONS

 outset of this paper I stated three aims, and it to be considered how far these have been

ıpid Control and Cure.—The present series rates that speedy control of acute mastitis can ved by the exhibition of systemic penicillin if it is started at the first sign of inflammation. It m belief that if all cases of acute mastitis are so th no breast abscess need ever occur.

inimal Interference with Breast-feeding.—It has wn that not only is weaning unnecessary but in disease is easier to control if the flow of milk is ed.

inimal Scarring in Cases requiring Drainage.— d of incision has been described which provides e drainage with minimal damage to breast tissue ch leaves an almost invisible scar.

SUMMARY

periences in the treatment of 153 cases of acute are described.

e *Staphylococcus aureus* was the commonest e organism.

lk stagnation was one of the most important in the ætiology.

the earliest sign of possible acute inflammation east, a course of systemic penicillin should be

there is any induration in the breast immediate should be practised.

new method of incision is described which gives llent cosmetic result.

ute mastitis is no bar to the continuance of eeding.

—Recent reports (e.g., Jones and Shooter 1948) that in the near future the use of watery solutions of n may give way to single daily injections of about units of procaine penicillin. Such an advance would loubly easy the treatment of acute mastitis by the practitioner.

h to record my grateful thanks to Mr. C. H. Walsh, ., and to Mr. J. Cosbie Ross, F.R.C.S., who gave me ion and encouragement to treat cases in their wards.

HÆMOPHILUS INFLUENZÆ MENINGITIS TREATED WITH STREPTOMYCIN

CHRISTOPHER OUNSTED
B.A., B.M. Oxfd, D.C.H.
PÆDIATRIC RESEARCH ASSISTANT, OXFORD REGIONAL HOSPITAL BOARD
From the Radcliffe Infirmary, Oxford

THE treatment of *Hæmophilus influenzæ* meningitis, once purely palliative, is now complicated by an *embarras de richesse* of many different specific agents. Sulphonamides, rabbit serum, penicillin, and streptomycin are the chief drugs in use. Cures have been reported with each of these, alone and in almost every possible combination (Alexander 1944, Alexander et al. 1946, Alexander and Leidy 1947, Grelland 1946, Smythe 1948, Gottlieb et al. 1947, Weinstein 1946, Nussbaum et al. 1946, Zinnemann 1946).

In the cases reported here the value of streptomycin was confirmed. Dosage was sometimes slightly higher, and duration of treatment longer, than those suggested by the Medical Research Council (1948a). The clinical progress of the child, rather than the bacteriology of the cerebrospinal fluid (C.S.F.), was the criterion by which treatment was regulated. A detailed investigation of the mental and physical condition of the children was also made $3^1/_2$ to 17 months after the end of treatment to assess the late results.

THE PATIENTS

Between July, 1947, and November, 1948, ten children with meningitis due to *H. influenzæ* were admitted to the Radcliffe Infirmary. This represents a hospital increase in the incidence both absolutely and relatively to other forms of non-tuberculous meningitis (table I). The increase may have been due to several factors: the availability of streptomycin solely at the central hospital, improved diagnosis, and, perhaps, a true rise in the incidence. Grelland (1946), in Norway, and Engbaek (1948), in Denmark, have found similarly that hæmophilus meningitis is increasingly diagnosed in their respective countries.

TABLE I—HOSPITAL ADMISSIONS FOR MENINGOCOCCAL AND *H. influenzæ* MENINGITIS IN CHILDREN UNDER THE AGE OF 14

Organism . .	*H. influenzæ*		Meningococcus	
Period . . .	1938–46	1947–48	1938–46	1947–48
Total cases	13	11	94	18
Percentage of all forms of non-tuberculous meningitis in children	7 %	30 %	50 %	49 %

Epidemiology.—The scatter in time and space was such that no connexion between one case and another was established. In no case had any member of a patient's household had any known illness in the two weeks preceding that patient's admission. The families from which the children came averaged 4·3 children apiece. No patient had less than two elder siblings; the significance of this fact is being investigated.

Age.—The eldest patient was aged 3 years; six patients were aged less than a year. This is the usual age-distribution of the disease in this country.

Course before Admission.—The onset had usually been insidious. The average duration of definite symptoms before admission was 7·5 days (in eighteen meningococcal cases admitted in the same period the corresponding figure was 3·8 days). The earliest and most constant symptoms had been drowsiness and irritability; these had been specifically noted in nine of the ten cases. Neck stiffness had been noted on the first day in two cases, both of them severe, and two children had had relatively narrow opening to a large central cavity. The earlier treatment had silenced the symptoms at the cost of a maimed breast.

It has been suggested that incision may be avoided by aspiration of the pus and instillation of penicillin into the abscess cavity (Florey et al. 1946). This technique was tried in 5 cases. The abscess was entered with a large-bore needle and as much as possible of the pus aspirated: 10,000 units of penicillin in about 10 ml. of water were instilled into the cavity. This was repeated daily as long as there was any pus. It was soon obvious that this method was open to many objections: the discomfort to the patient was considerable; it was difficult if not impossible to secure complete evacuation of pus; and it is often impossible to empty all loculi without considerable probing with the needle, which (to be effective) requires a general anæsthetic, thus nullifying what is said to be one of the chief advantages of this technique. The following case-history illustrates these objections:

A primipara, aged 26, was admitted six weeks post partum. A tender swelling below the left nipple, present for ten days, had been treated by her doctor with sulphonamides and poultices with no improvement. The abscess, 7 cm. in diameter, was below the areolar margin at 6 o'clock in the left breast. No constitutional disturbance.

Intramuscular penicillin, 20,000 units four-hourly, was begun. Using a large-bore needle attached to a 20 ml. syringe, about 20 ml. of thick pus was withdrawn and 10 ml. of a watery solution of 10,000 units of penicillin was inserted into the cavity. Pus gave on culture a pure growth of coagulase-positive penicillin-sensitive *Staph. aureus.*

Dec.	16,	25	ml.	pus aspirated	Penicillin 10,000 units (in 10 ml. water instilled each day
,,	17,	18	,,	,, ,,	
,,	18,	23	,,	,, ,,	
,,	19,	40	,,	,, ,,	10,000 units in 25 ml.
,,	20,	7	,,	,, ,,	10,000 units in 5 ml.
,,	21,	2	,,	,, ,,	

On Dec. 22 the abscess was re-forming. Under thiopentone anæsthesia a stab incision was made at 6 o'clock at the areolar margin. Very thick pus evacuated. All thickened zones entered with sinus forceps and pus expressed. A Charrière rubber catheter (no. 10) led into cavity. Culture of the pus obtained on this occasion gave again a coagulase-positive penicillin-sensitive *Staph. aureus.* On the 24th improvement was considerable and induration almost gone. Systemic penicillin was stopped. On the 27th all inflammation was resolved; very slight serous discharge around catheter. The catheter was removed and the patient went home. On the 30th the wound was healed, with only slight residual thickening.

Of the other 4 cases treated by the aspiration technique, 1 required incision on the sixth day and the remaining 3 were apparently resolved on the fourth, fifth, and ninth days. Repeated aspiration is inefficient and is very unpleasant for the patient.

At first the cases needing drainage were dealt with by the classical radial incision. In the main this incision is satisfactory, but sometimes the scar is very unsightly. In an effort to improve the cosmetic result I adopted for a while a curved incision in the submammary fold. Entirely contrary to my expectations this incision was very slow to heal, chiefly because the upper lip, borne down by the weight of the breast, tended to slide down and override the relatively fixed lower lip. The consequent difficulty in maintaining apposition of the healing edges, combined with the almost inevitable low-grade sepsis in the wound, made union slow and unsatisfactory. This incision has been advocated for a retromammary abscess but no such case was encountered in the present series.

A further objection to both the long radial and the long submammary incision was soon apparent. 5 cases treated thus were secondarily invaded by a hæmolytic streptococcus and in all 5 this caused a considerable delay in healing. Obviously the length of the incision cannot be held solely responsible for such invasion—but the risk would seem much less with small incision.

Observing that the majority of neglected ab tend to point at the areolar margin, or close to it, tried an incision about 1 cm. long placed the areolar margin. To avoid duct damage this is made through skin and superficial fascia through it a long pair of narrow-bladed ar thrust into the abscess cavity. By palpating instrument with the left hand laid flat on the indurated areas and loculi can be entered and As much as possible of the pus is expressed (danger of disseminating infection if preoperative has been given). A small rubber tissue drain is for twenty-four hours, a dry dressing is applied, breast so bandaged as to keep it well supported. penicillin, 100,000 units eight-hourly is gi first dose being ad tered with the operative atropine. Florey has shown this dosage of peni adequate to maint bacteriostatic conc tion in any we exudate.

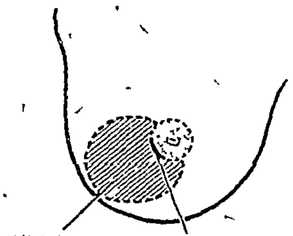

Fig. 1—Incision exactly on areolar margin.

The technique illustrated in figs. 1

In this series abscesses were tr in this fashion, in them the average time from incision to co healing was 6·9 days. Usually the wound was dry fourth day, when administration of penicillin was st In all these cases emphasis was laid on manual exp *of all milk in the infected breast,* as previously des In none of the 31 did a secondary abscess develop. a cosmetic point of view this incision is very satis the scar being almost invisible after a couple of So satisfactory have I found it that I would recom its adoption for any abscess near to the areola. F few cases in which the abscess is near the periph in the axillary tail, the same technique can be fo

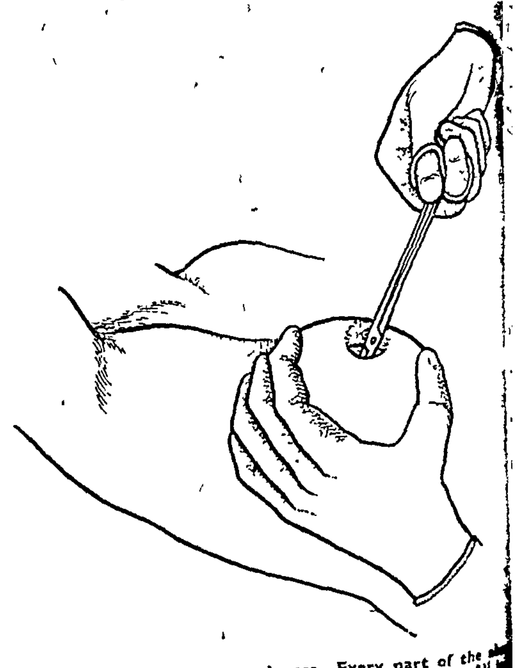

Fig. 2—Forceps about to enter abscess. Every part of the should be palpated against the point of the forceps. All (also any "lactoceles") can thus be felt and entered.

TABLE IV—STATE OF CHILDREN 2½–15 MONTHS AFTER DISCHARGE FROM HOSPITAL

Age	Months since discharge	Weight (lb.)	History and physical findings	Intelligence and behaviour pattern	C.S.F.		Fasting sugar levels (mg. per 100 ml.)		Cold caloric test	
					Cells per c.mm.	Protein (mg. per 100 ml.)	C.S.F.	Blood	Right	Left
3 yr. 2 mos.	12	31½	? Petit mal; healthy child	Advanced for age	1 lymph	16	67	90	Normal	Normal
3 yr. 10 mos.	9	35¼	Normal development, healthy child	Advanced for age	7 lymphs	28	67	75	Normal	Normal
1 yr. 9 mos.	10	24¾	Normal development, healthy child	Average for age	1 lymph	21	65	103	Normal	Normal
1 yr 8 mos.	10	25½	Transient external squint, healthy child	Slightly below average	3 lymphs	32	57	66	Normal	No response
2 yr. 4 mos.	14	33¼	Normal development, healthy child	Average for age	2 lymphs	31	59	70	Normal	Normal
2 yr.	15	27	Normal development, healthy child	Slightly below average	..	..	..	..	Normal response to rotation	
1 yr. 3 mos.	11	22½	Normal development, healthy child	Average for age	1 lymph	38	55	75	Normal	Normal
1 yr. 11 mos.	2½	28¼	Normal development, healthy child	Average for age	17 lymphs, 2 polys	35	44	65	No response	No response
2 yr. 10 mos.	2½	28	Normal development, chronic eczema, facial paresis	Advanced for age	7 lymphs	50	57	79	No response	No response

The radiographic appearances of the skull were normal in all cases.

OUTCOME

ne patients recovered, and one died. To assess the results of treatment the surviving children were itted again 2½–15 months after discharge from ital (table IV).

ental Development.—A detailed account of the child's vas obtained from the mother. The early histories e elder siblings, of whom there were not less than in each case, were also taken and used as controls in each family. The patients were then observed idually for 45 minutes to an hour with their mothers, for a further 4–5 hours alone and with other children. pattern of their behaviour, their dexterity and bulary, their ability to solve simple problems, their ions to strange situations, and the variations and sity of their emotional tone were noted. In no did these observations reveal any significant tion from the normal range.

ysical Development.—Physical examination revealed ntirely normal child in all except case 9, who had a -sided supranuclear facial paresis when seen 2½ ths after discharge; this had resolved completely nths later. Case 1 gave a history suggesting petit during the first 3 months after discharge from ital, when six episodes were seen by her parents. ach she stopped her playing suddenly, squatted, d vacantly into space, and did not respond to her e or to shaking. Within 2 minutes she had returned rmal. The attacks did not recur during the subset 9 months, and an electro-encephalogram taken at nd of this time gave no evidence of epileptic activity. onal' electro-encephalograms were made also of the survivors; there were some minor abnormalities no evidence of gross cerebral damage. Skull radios showed no spreading of sutures. The C.S.F. was al apart from a slightly raised C.S.F.-protein level a few lymphocytes in some cases (table IV).

CASE-RECORDS

e two cases which took an unusual course under ment were as follows:

se 6.—A boy, aged 9 months, the fifth child of healthy nts, had been quite well until 2 days before admission, he had become drowsy and later had a brief convulsion. day he had been more drowsy, had vomited his milk, ad several small fits. His family doctor had found fever stiff neck and sent him to the local hospital. A lumbar ture had produced C.S.F. under an initial pressure of mm. C.S.F. and 8 ml. of turbid fluid had been removed, from which a profuse growth of *H. influenzæ* was subsequently obtained. The patient had been given intramuscular 'Sulphamezathine' 1 g. followed by 0·25 g. three-hourly thereafter, and penicillin 50,000 units three-hourly. That same evening a second lumbar puncture had found the pressure low and very little fluid obtainable. Next day the patient was transferred to the Radcliffe Infirmary.

On admission on Nov. 21, 1947, at 2 P.M. he was a large, well-nourished, and well-hydrated baby, conscious and crying vigorously. There were slight head retraction, definite neck stiffness, and a slightly bulging fontanelle; the limbs were hypotonic. During the examination the patient had an attack; he suddenly became blue-grey, rolled his eyes upwards and outwards, and appeared to become unconscious. Within a few minutes his colour returned and he again

convulsions. Apart from fever, signs of pneumonia in one case and of otitis media in one other, no other definite physical signs had been reported by the family doctors. The patients had tended to become progressively more ill until admission, though the disease had been notably modified when intensive penicillin or sulphonamide therapy had been given.

Condition on Admission.—The clinical picture on admission was fairly uniform. The children were febrile, drowsy, and irritable. Nuchal rigidity was found in every patient and, apart from bulging of the fontanelle, was the only neurological sign in nine cases; there were other signs in the only fatal case (case 10 below). Disease of other systems was found in three cases: bilateral otitis media once, and pneumonia of a lower lobe twice. The children were well nourished, and dehydration needing intravenous fluid was not seen. Considered solely in terms of their appearance the children were classified as severely ill, three; moderately ill, five; and mildly ill, two. The initial findings in the C.S.F. varied widely (table II). The general pattern was polymorph pleocytosis, with a considerable increase in protein; sugar was diminished or (by the non-quantitative test used) absent. *H. influenzæ* was seen in films and was grown from the first lumbar specimen in each case; this was the sole criterion of diagnosis. Other initial investigations showed the expected polymorph leucocytosis in the blood, with a mild hypochromic anæmia. Chests radiogram showed a distinct pneumonia once, and increased basal markings once; otherwise there were no significant abnormalities. Patch tests were uniformly negative. No pathogenic organisms were isolated from throat or nasal swabs. Bloo not made.

TREATMENT

The intramuscular dosage of streptomycin was adj roughly to be 20,000 units per lb. of body-weight as suggested by the Medical Research Council (1 Individual intrathecal doses were sometimes higher those recommended; six patients received 50,000 daily, and four 75,000 units daily (table III). The of streptomycin treatment was determined by condition of the patients rather than by the of the C.S.F. In five cases treatment was more than 7 days after the first sterile C.S.F., receiving 45 days' intramuscular and 15 days' treatment. In addition, sulphadiazine was used in cases, and penicillin was added in one case. barbitone gr. $^1/_8$–$^3/_4$ t.d.s., the dosage varying with was given routinely as prophylaxis against convul since in infants fits may be fatal; two children had fits before admission; and no fits were seen after ph barbitone had been given. Ferrous sulphate was g in four cases as treatment for anæmia.

PROGRESS

The assessment of progress fell under three hea progress by the third day; progress between the and the eighth day; and progress thereafter. first had a fairly well-marked pattern in C.S.F. cha the second was the period of clinical resolution, and third was not clearly defined.

By the Third Day.—In all cases the C.S.F. was st at the end of 48 hours' treatment. By the third there was an obvious fall in temperature and in amount of protein and white cells in the C.S.F., wi rise, usually of about 25–50%, in the percentag lymphocytes.

Between the Fifth and the Eighth Day.—This was period of clinical resolution: neck stiffness, drowsin irritability, and evidence of toxæmia disappeared; children became lively and alert; and their we began to rise.

Thereafter.—From the 8th day onwards progress more difficult to assess. Clinical examination did reveal any striking changes. The temperature, exc in 2 cases, remained normal. The C.S.F. was abnormal as regards cells, protein, and, sometim sugar. The figures for cells and protein varied wi from case to case; in any given case the total num of cells showed a slow decline, with a corresponding in the percentage of lymphocytes. The amoun protein declined in parallel with that of the cells, graphs tending to an exponential type of curve. C.S.F. remained mildly abnormal in several cases 90 days after the institution of treatment (table IV).

TABLE II—INITIAL FINDINGS IN TEN CASES OF INFLUENZAL MENINGITIS

Case no.	Age	Day of disease	Clinical severity	Blood		Cerebrospinal fluid				Sensitivity of organism to streptomycin (units per ml.)	Chemotherapy before admission

10	10 mos.	21–25	Severe	20,000	68	500	3000	35	+	..	Penicillin 1,440,000 i.m. Sulphadiazine 12

mides or with rabbit serum in the remainder. ledical Research Council (1948b) reported thirty- complete recoveries in fifty cases treated with omycin. Since the present series ended there been four further cases at the Radcliffe Infirmary, covering completely. The recovery-rate in our al is now therefore 93%—i.e., thirteen in fourteen cutive cases.

TREATMENT AND PROGNOSTIC SIGNS

e treatment of *H. influenzæ* meningitis is still imental, and the prognostic signs by which it is to dged have not yet been fully assessed. Sterility of .S.F. for 7 days does not necessarily indicate that ion is at an end (Smythe 1948, Medical Research cil 1948b). The persistent abnormality in the C.S.F. and to a less extent in protein in this series (table IV) have been due to a mild chemical meningitis induced reptomycin, but an early and continued rise in the ntage of lymphocytes ran parallel with clinical ovement.

e did not use the quantitative sugar test during the phase in this series. This estimation has been l of great value by Alexander (1944) and Alexander . (1946) both in the assessment of severity and guide to progress. Smythe (1948) found, however, some clinically severe cases had normal C.S.F.-sugar s. Brøchner-Mortensen et al. (1948) did not find C.S.F.-sugar level a reliable guide. There seem to wo possible factors, apart from the disease process , which might cause unexpected variations in the r levels :

Alvaro and Nicola (1948) showed that streptomycin was ucing agent, particularly when diluted. They suggested sugar estimations during streptomycin treatment were fore unreliable. Nitti and Curci (1947) had already n that 1 g. of streptomycin had a reducing effect equiva- to that of 0 44 g. of sugar. However, Mr. E. J. Higgins onal communication 1949) has shown that a concentration reptomycin 500 units per ml. has a reducing effect alent to that of 10 mg. of glucose per 100 ml. in water. last observation suggests that, under conditions obtaining actice, the direct effect of streptomycin on the apparent sugar level is negligible.

Parallel studies on blood-sugar levels are not commonly rted. The recovered cases in this series showed a mean ng blood-sugar : C.S.F.-sugar ratio of 1·33, with a range 58–1·12. Katzenelbogen (1936) showed that the C.S.F.- r level was determined by several factors, of which the l-sugar was, in health, the most important. The range rmal values was wide. When the meninges are inflamed, tional factors operate. The number of leucocytes, the ence of organisms, and changes in the permeability of the d-brain barrier may each independently affect the sugar es.

stimation of the C.S.F.-sugar level after a twelve-hour and with a parallel estimation of the blood-sugar as likely to eliminate factors outside the central ous system. When this precaution is not taken, lerline figures and small variations seem to be of btful significance.

homson et al. (1947) found that the temperature chart a reliable guide to progress, and certainly in eight of ten cases there was a steady decline in fever following institution of treatment. Probably the child's ntal condition, weight, and temperature, taken ether and in the absence of intercurrent infections, a reasonable measure of the success of treatment.

COMPLICATIONS

here were few complications in this series. Drug- stant organisms were not encountered : we did not t the arthritis described by Smythe (1948), nor were re any serious residual lesions. The possibility of rcurrent infections, particularly with *Staph. aureus,* emphasised by Weinstein (1946), and such an infection probably occurred in case 6, penicillin rapidly controlling the infection.

Spinal block has been reported by Alexander (1944) in patients treated with serum, by Jones (1947) in those treated with penicillin, and by the National Research Council (1946) in those treated with streptomycin. Alexander (1944) has treated this complication successfully with heparin and air injections. However, St. Hill et al. (1948) have shown that commercial streptomycin (calcium complex or hydrochloride) precipitates heparin, unless special precautions are taken. Complete spinal block occurred twice in this series. In both cases intrathecal treatment was continued through bifrontal burr-holes into the lateral ventricles. In the patient who survived, the use of the lumbar route was resumed in 3 days.

All the nine survivors had tests of vestibular function during the follow-up period. Cold caloric tests did not elicit a response in cases 8 and 9. These two children were tested the shortest time of any after the end of streptomycin treatment and, though they had been given streptomycin for only 8 and 7 days, their C.S.F.-streptomycin levels were exceptionally high (table III). Brown and Hinshaw (1946) found that the toxic action of streptomycin on the eighth nerve was invariably slight in the young, and in only 1 in 23 in their series did symptoms appear in less than 2 weeks of treatment. Five of our nine survivors received intramuscular streptomycin for 12 days or more ; one of these showed an absent caloric response on one side. The responses of three more were normal. One child was not tested, but he showed a brisk vestibular response to rotation. None of the children had symptoms of vestibular damage, and none of them was deaf.

Penicillin in moderate dosage had been given to five of our patients before admission (table II). In no case, however, had the C.S.F. been sterilised. Previous experience in this hospital confirms the opinion of Gottlieb et al. (1947) that penicillin is efficient only when given in massive dosage. Penicillin therapy has the further disadvantage that the in-vitro sensitivity of the organism bears little relation to the clinical response.

CONCLUSIONS

Streptomycin is an efficient remedy for *H. influenzæ* meningitis. The duration and intensity of treatment are best decided on clinical assessment of each patient. Larger doses and longer courses than those usually recommended can be used with safety. The use of sulphadiazine gives an additional safeguard against drug-fast relapses, and phenobarbitone is a useful safeguard against fits. Spinal block requires prompt surgical treatment. The combination of streptomycin and sulphadiazine is, in our opinion, the treatment of choice. When streptomycin is unobtainable, massive penicillin therapy is useful.

SUMMARY

Ten cases of hæmophilus meningitis are described. Treatment with intrathecal and intramuscular streptomycin, together with sulphonamides by mouth, was successful in nine cases, and a further three cases have since made complete recoveries.

The child's general condition is the best guide to progress.

Mental and physical development of the survivors was studied $2^1/_2$–15 months after discharge, and no significant retardation was found.

I wish to thank Dr. V. Smallpeice, under whose care these patients were treated, for encouragement and permission to publish. My thanks are also due to Dr. Dawn Bosanquet and Mr. E. J. Higgins.

References at foot of next page

appeared to be conscious. Phenobarbitone gr. 1 was given intramuscularly, followed by gr. 1/2 eight-hourly.

Lumbar puncture at 6 P.M. produced a very sluggish flow of C.S.F. through a wide-bore needle. Suction was applied without success. The child at once became limp and grey, with pin-point pupils and shallow irregular respirations. Within half an hour he recovered his former state.

At 7 P.M. bifrontal burr-holes were made. Needling of the ventricles gave a turbid C.S.F. under a pressure of 230 mm. C.S.F. Streptomycin 50,000 units was injected into the left ventricle. Intramuscular streptomycin 150,000 units eight-hourly and sulphadiazine 0·75 g. four-hourly were given. At 10 P.M. the child was more ill and drowsy, with a temperature of 104°F.

On Nov. 22 his general condition was better, though the meningitic signs were more marked. He was taking feeds well, and his temperature had fallen to 102°F. Streptomycin 25,000 units was given into the lateral ventricle.

Radiography at this time showed no abnormality in chest or skull, save for a little air in the left lateral ventricle.

Blood examination showed Hb 10·9 g. per 100 ml., and leucocytes 13,000 per c.mm. (neutrophils 6890, lymphocytes 5460, monocytes 520).

On Nov. 23 the C.S.F. had been sterile for twenty-four hours and showed a considerable fall in the amounts of protein and cells; the child had clinically improved, and his neck stiffness and photophobia were less. Lumbar puncture on Nov. 24 produced a free flow of C.S.F., and thereafter all intrathecal streptomycin was given by this route.

By Nov. 29 the child was playing and laughing, though his temperature was still raised. Since the lumbar C.S.F.-streptomycin levels had been low (3–8 units per ml.) on the previous days, 25,000 units was given twice daily from Nov. 30 to Dec. 2, and on Dec. 2 the level was 41 units per ml.

On Dec. 6 intrathecal streptomycin was stopped. In the next four days the patient lost 17 oz. in weight. On Dec. 10 he became listless, irritable, and febrile, and on Dec. 12 he began to vomit and was still losing weight. His neck became stiff, and the left frontal burr-hole was swollen. The C.S.F. remained sterile and showed a slight rise in the amount of protein, but none in that of the cells. Systemic penicillin was given, and within a few days all these symptoms subsided, without their significance being fully understood.

Discharge and Follow-up.—The patient was discharged on Jan. 22, 1948. He was re-examined on May 3, 1949 (15 months later), and was then a normal child, with manipulative ability in advance of his age and with speech of slightly less than average development. There were no residual lesions.

In this patient the disease ran a protracted course (see figure) and was complicated by convulsions and by spinal block, which was circumvented by prompt ventricular streptomycin treatment. The patient received 15 days' intrathecal and 45 days' intramuscular streptomycin. The infecting organism was sensitive to a streptomycin level of 0·6 unit per ml. Four days after intrathecal streptomycin was stopped the patient had an attack resembling a hydrocephalic attack, which subsided without any treatment other than systemic penicillin. In spite of all these factors recovery was complete.

The next case was the only fatal one of the series:

Case 10.—A girl, aged 10 months, the fifth child of healthy parents, had been normal during her first 9 months of life. Sixteen days before admission she had been feverish, vomited several times, and appeared to have pain in her right ear. Fourteen days before admission bilateral paracentesis of the drums had been performed, and she had been given intramuscular penicillin 80,000 units three-hourly and sulphadiazine 0·25 g. by mouth four-hourly. Her general condition had improved, and her temperature had fallen. Eight days before admission chemotherapy had been stopped. Two days later the girl had begun to vomit, her temperature had risen, and her general condition had declined. Next day chemotherapy had been given again as on the previous schedule. Five days before admission neck stiffness had been found for the first time and, on lumbar puncture, a purulent fluid containing *H. influenzæ* had been obtained. Penicillin had been discontinued next day. Thereafter there had been a steady deterioration in the general condition and an increase in the meningitic signs.

On admission at 4.30 P.M. on July 7, 1947, she was a pallid ill child, weighing 16 lb., with a temperature of 101·2°F, respirations 42 per min., and pulse-rate 146. Both showed chronic congestive changes. There were well head retraction and neck stiffness, a bilateral external palsy, and, probably, complete blindness. All refle increased, and both plantar responses were extensor.

Lumbar puncture produced a cloudy C.S.F. 500 mg. of protein per 100 ml., 3000 white cells per (lymphocytes 65%), and a few gram-negative rods. gave a moderate growth of *H. influenzæ*.

Blood-count.—Hb 10 g. per 100 ml. (68%); red 3,900,000 per c.mm., white cells 20,000 per c.mm. (ne 12,000, lymphocytes 6800, monocytes 1200).

Radiography of skull and chest revealed no ab

Treatment.—Intrathecal streptomycin 50,000 units muscular streptomycin 100,000 units were given eight Phenobarbitone gr. 1/8 t.d.s. was given in feeds. On 1947, there was a slight improvement. The patient's perature was 99°F. She took three feeds by mouth vomited but little. On that day, at 2.45 P.M., lum yielded only 0·5 ml. of C.S.F., and there appeared a spinal block; streptomycin 50,000 units was The aspirated fluid was sterile on culture and con streptomycin 2 units per ml. and 5000 white cells per (lymphocytes 51%).

Operation.—About six hours later Sir Hugh Cairns bifrontal burr-holes, and both lateral ventricles were ta The ventricular pressure was 580 mm. of C.S.F. The from the right ventricle contained protein 60 mg. per 10 cells 60 per c.mm. (polymorphs 27, lymphocytes 33 streptomycin 2 units per ml. Streptomycin 75,000 unit introduced into the right ventricle. Next day the p seemed to be improving in the morning, but in the afte she suddenly stopped breathing and died.

Necropsy Findings (Dr. Dawn Bosanquet).—Apart chronic bilateral otitis media there were no macro lesions outside the central nervous system. Macroscop there was a gross meningitis with thick pus over the b the brain and down the spinal cord. The frontal showed microscopically a little infiltration of the pia arac over the convexity of [illegible] in the sulci. The e[illegible] macrophages, and round cells. There was no obvious of the superficial vessels in the brain, but the section in a small piece of ependymal surface, and here there granular ependymitis. Beneath this the subepend vessels showed a well-marked cuffing, with monon cells. The pons showed microscopically a surface co with a fairly thick exudate. The penetrating vessels pons had exudate in the Virchow-Robin spaces in the ficial part of their course. Beneath the ependyma fourth ventricle the cuffing of the vessels was very spicuous, though the ependyma appeared normal. The superficial layer of the adventitia of the basilar artery slight infiltration with inflammatory cells, though the intima and media appeared normal. In some of the branches the whole thickness of the adventitia was infilt though again the media and the intima appeared unaff The spinal cord showed microscopically a severe ph with thrombosis, but no arteritis except for slight infilt of the adventitia of some of the arteries. In the lu region a few of the anterior-horn cells showed loss of substance and eccentricity of the nuclei. Here there much exudate, of which all the superficial part was ne In the cervical region the nerve-roots were surround exudate, but generally this was much less than in the lu region—a characteristic finding in purulent meningitis.

In this case partial control of the infection by quate chemotherapy led to a chronic meningitis spinal block. Effective chemotherapy was begun late to influence the outcome. Death resulted fro acute hydrocephalic attack.

MORTALITY

The case-mortality from hæmophilus meningitis slowly declining when Alexander (1944) reported th of specific rabbit antiserum combined with su diazine; among eighty-seven cases she had sixty- recoveries. The National Research Council (reported a hundred cases in which streptomycin used, with a 66% recovery-rate; streptomycin was alone in eighteen cases, and in combination with d by a smooth recovery until a pulmonary embolus his life on the 16th postoperative day.

ugh this case was an exception, most surgeons gree that resection of mobile growths of the stomach traightforward procedure compared with resection ne of the penetrating simple lesions which are met This was found to be so in the other malignant ir in our series, which is included as an example bizarre.

e 6.—A woman, aged 42, gave a history of recurrent emeses for 12 years. X-ray examination outlined a defect in the body of the stomach, and a further temesis hastened operative intervention, subtotal ctomy being performed. The resected portion of ch contained an ulcerated growth the size of a tangerine. ved to be a malignant neurinoma.

THE OPERATION

re is no doubt that, wherever possible, partial ctomy is the operation of choice. Alternative dures are ligation of main vessels supplying the area, transgastric ligation of a bleeding-point or fixion and infolding of the ulcer, and resection of ase of the ulcer leaving the crater adherent to rrounding structures and sewing up the hole in the ch.

regards ligation of a spurting vessel, it is notorious a bleeding-point is seldom found when sought, t ligation of the vessels supplying the ulcer crater ghly unsatisfactory as a means of stemming the indeed when both gastric and both gastro-epiploic es are ligated during gastrectomy, the stomach wall leeds vigorously when incised, and those who have ised devascularisation of the stomach as a method ducing acidity know how difficult it is to effect isfactory ischæmia. Resection of the ulcer base closure of the hole in the stomach will control the rrhage, but with the large penetrating posterior ic ulcer, where the surgeon would welcome an native to gastrectomy, it is often only after division e duodenum, enabling the body of the stomach to fted up, that the crater can be resected and the ng in the stomach closed.

se 7.—A woman, aged 56, with a large chronic gastric confirmed by radiography, refused operation and took lischarge. A week later she was readmitted, exsan-ted after a gross hæmatemesis. Operation revealed midable ulcer on the posterior wall of the stomach. rating the transverse mesocolon and pancreas and ding an indeterminate distance towards the fundus. duodenum was divided and the ulcer base cut away the stomach wall, the upper limit being reached after ion on the elevated body of the organ. A hole in the rior stomach wall the size of a five-shilling piece was up, and a high partial gastrectomy performed with the f a Petz sewing clamp. Recovery was uneventful.

e alternative to partial gastrectomy most commonly ised is probably transgastric or transduodenal sfixion of the ulcer bed. This is open to the serious ction that the ulcer is neither put at rest nor removed the digestive action of the gastric juice—two ntials in the satisfactory control of hæmorrhage. ractice, partial gastrectomy is the only operation h offers a guarantee that no further hæmorrhage will r, and the surgeon should not easily be deterred it by considerations of age or unfitness.

ase 8.—A frail, thin woman of 77 had repeated hæma-es from a duodenal ulcer. Despite her poor condition rtial gastrectomy was performed. Recovery followed.

hen a transfixion operation has been carried out the patient continues to bleed, the surgeon is in an ious position and may have to consider gastrectomy a deteriorating subject. The following case shows well unreliability of ulcer transfixion and the possibilities a successful resection in the most unfavourable circumstances. I am indebted for details to Mr. John Scholefield, F.R.C.S., who performed both operations.

Case 9.—A man, aged 43, was admitted in a state of collapse, with extreme pallor and black stools. Previous investigation had suggested a gastric ulcer, and there was little doubt about the nature of the catastrophe. He was treated by massive drip-transfusion, but after two days he had a further large melæna and operation was undertaken forthwith. On opening the abdomen an enormous gastric ulcer was located just proximal to the pylorus which was widely open. There was much altered blood in the intestines and it was obvious that the hæmorrhage was coming from the gastric ulcer. This was a deeply penetrating ulcer and its removal would have been an operation of some magnitude, for which the patient was quite unfit. The stomach was opened and deep sutures passed through the base of the ulcer so that the cavity was obliterated. The hole in the stomach was then closed in the transverse diameter.

Four days later it was noted: "This patient has had a further hæmorrhage today and is obviously going to die unless further surgery is undertaken. He is an exceedingly poor risk for surgical treatment." The abdomen was reopened the same day and a rapid partial gastrectomy performed, the base of the ulcer being left on the pancreas. During this procedure the bleeding vessel was seen spurting in the *middle of the ulcer base and was ligated. It was difficult* to identify but was thought to be either the gastroduodenal artery or the superior pancreaticoduodenal artery.

After this major intervention the patient made a complete recovery, a tribute to the courage and resource of the surgeon.

THE NEGATIVE EXPLORATION

Sometimes, when the abdomen is opened, the anticipated ulcer is neither seen nor felt and no other obvious cause for the hæmorrhage is found. It has been suggested by Amendola (1949) that in these circumstances the stomach and duodenum should be widely opened, the cavity washed out with saline, and the bleeding-point sought: if the bleeding-point is not found, the incision in the stomach is sewn up and the abdomen closed. This plan cannot be recommended: it is difficult to see how gross soiling can be avoided and there can be no guarantee that an erosion will not be missed.

Simply to close the abdomen, having found nothing, is a council of despair and likely to cause embarrassment if a further hæmorrhage occurs. We have had three cases in this unit where careful external examination of the stomach and duodenum did not reveal any abnormality and yet a lesion was found in the resected stomach. Two were acute ulcers with erosion of a blood-vessel; details of one of these will suffice.

Case 10.—A man, aged 52, had had slight dyspepsia for three days. Two days before admission he collapsed and "passed out" and after coming round he had a very large hæmatemesis. After a further hæmorrhage he was admitted in a desperate condition. He received three pints of blood immediately, followed by a continuous drip-transfusion, and was prepared for surgery. Nothing was found on examination of the stomach or duodenum except a few adhesions in the lesser sac and some enlarged glands on the lesser curve. A high partial gastrectomy was carried out; the resected stomach contained multiple erosions in one of which was the orifice of a large vein plugged with clot.

The third case in which there was a shallow chronic ulcer on the posterior wall of the stomach, bears out the fact, which we have previously observed, that some chronic ulcers cannot be felt until the stomach has been widely mobilised.

Case 11.—A woman, aged 55, had been treated for six years for indigestion and hæmatemeses. Three weeks before admission she was involved in an accident and suffered from an exacerbation of her symptoms until the day of her admission when she vomited up a large quantity of blood and felt faint. In view of the strong presumptive history of peptic ulcer, her age, and the fact that she had had several previous hæmatemeses, operation was performed the same night. The stomach and duodenum appeared normal; nevertheless a high resection was carried out and on opening the specimen

SOME PROBLEMS OF EMERGENCY GASTRECTOMY FOR HÆMATEMESIS

LOUIS A. IVES
M.B. Lond., F.R.C.S.
CHIEF ASSISTANT IN SURGERY, WEST MIDDLESEX HOSPITAL

SEVERAL reviews of urgent partial gastrectomy have been published (Gordon-Taylor 1946, Tanner 1949), and gastro-enterologists are increasingly conscious that surgery offers the best chance of survival—in a selected group of patients. Thanks to continuous-drip transfusion, introduced by Marriott and Kekwick (1935), the exsanguinated case is now a rarity; but many surgeons dislike having to deal with a patient with much foreign blood in his veins, believing that those who are sent for surgical intervention at an early stage in the crisis have a smoother postoperative course. The *problem of whether and when to operate remains* the attendant physician's greatest anxiety.

SELECTION FOR SURGERY

At the West Middlesex Hospital our cases are primarily admitted under the care of the physicians, who call in the aid of surgery when they think fit. Our experience is strongly in favour of this arrangement, which is probably in force in the majority of hospitals in this country: provided there is accord between the medical *and surgical staff, it is better for these patients not to* be in the surgeon's charge from the start. Moynihan's ideal of the surgeon who is a physician trained in surgical methods is still far from being generally realised. I need scarcely add, however, that it is equally important for the physician to be cognisant of the benefits which on occasion surgery alone can offer.

The practice in our hospital is to advise surgery for a small group of hæmatemesis patients who present strictly limited indications for operation. These have been admirably summed up by Maingot (1941) and need not be elaborated except to say that we regard age as the most important single factor governing the decision to operate, and are in entire agreement with Avery Jones (1947) on this point. The object of this paper is to illustrate some of the diagnostic traps and technical *difficulties which have arisen in a small series of emer*gency operations for hæmatemesis done in a general surgical unit at the West Middlesex Hospital during the last twelve months.

It is generally agreed that before resorting to opera*tion there should be reasonable evidence of ulceration.* To ignore this would be to bring surgical treatment into disrepute; and yet we have had cause to regret our hand.

Case 1.—A man of 50 was admitted with No adequate previous history was admitted, and, a surgical opinion was sought, nothing beyond suggested an ulcer as the source. Further occurred while he was under medical treatment, and gastrectomy performed as a last resort failed to save The resected specimen showed multiple acute ulcers.

The diagnosis of ulceration may have to be on circumstantial evidence alone, and in several cases of successful resection the acute catastroph proceeded by nothing more definite than postp dyspepsia over a more or less lengthy period. other hand we have learned by bitter experience not every hæmatemesis patient with epigastric after meals has a peptic ulcer.

Case 2.—A man, aged 53, was under treatment in ho for erysipelas of the face when he had a sudden hæmatemesis. He was transferred immediately to our and further blood-loss was so great that exsanguination barely controlled by transfusion through two can A history of epigastric pain after meals for an inde period was elicited, and, though he was too ill to give acccurate acc [illegible] ulcer was thought be the likely [illegible] revealed ascites cirrhosis of t [illegible] d shortly afterw and a post-mortem examination confirmed rupture of œsophageal varix as the source of the hæmorrhage.

When previous radiographic evidence of an ul exists, a confident attack may be planned; yet even these circumstances the surgeon may be disconcert

Case 3.—A woman, aged 70, was admitted after a sev hæmatemesis. She gave a history of post-prandial pain many years, with occasional vomiting, and her doctor wa to say that when she was radiographed three months previo at another hospital the appearances were those of a gastric ulcer. After further hæmatemesis an urgent laparot with a view to gastrectomy was undertaken. On open the abdomen, clear fluid welled forth and a coarsely cirrh shrunken liver was seen. No abnormality was detected the stomach and duodenum, but a strong adhesion compre the lesser curve, and this may have been responsible for fallacious X-ray report.

After these two unhappy experiences the possibil of cirrhosis as a differential diagnosis has become mu more sharply defined, and we view the signs of *fluid in the abdomen with a jaundiced eye.* Neverthel not all gastric patients with shifting dullness in abdominal cavity are suffering from portal obstructi

Case 4.—A patient was admitted for routine par gastrectomy for chronic duodenal ulceration of many ye standing. *On opening the abdomen clear fluid* escaped, it was at first suspected that the anæsthetist had misdirec his infiltration fluid (!). Further examination showed source of the fluid to be a sizeable perforation in the standing ulcer. The patient did not complain of any pain wl waiting in the anæsthetics room, and the perforation must h occurred during induction of anæsthesia (regional block)

Duodenal and gastric ulcers compose the major of lesions in the stomach calling for resection. Fr hæmorrhage from a gastric carcinoma is rare, according to Bockus (1946) not more than 5% of cancers of the stomach have an overt hæmateme We have only one such case in this series, but the unus circumstances make it worth describing.

Case 5.—A man, aged 53, underwent a successful operat for strangulated inguinal hernia. He was a stout, sallow m but nothing untoward was noticed until the 6th day whe was remarked that he was rather pale. By the 8th day progressive pallor could not be ignored and he crystalli our anxieties by vomiting up a quantity of blood. On strength of a vague history of dyspepsia and loss of appe the abdomen was opened, and a large malignant ulcer *palpated on the lesser curve.* A subtotal gastrectomy

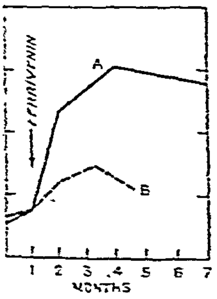
METHOD

e preparation used was ferrivenin. A test dose of g. was given to exclude patients who might be ly sensitive to the drug. The subsequent course sted of 5 daily doses of 200 mg. In one case there mild symptoms, which followed the 2nd dose of mg. and consisted of immediate flushing of the face slight bronchospasm lasting only a few minutes;



1—Average hæmoglobin el after administration ferrivenin: A, in 16 es which responded well; d B, in 7 cases with oor response.

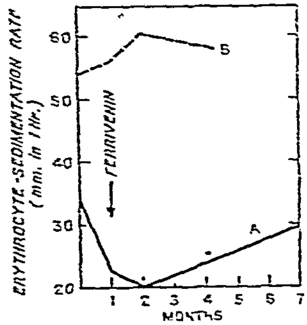


Fig. 2—Average erythrocyte-sedimentation rate (Westergren): A, in 16 cases which responded well to ferrivenin; and B, in 7 cases with a poor response.

quent doses were limited to 100 mg., but the final was raised to 200 mg. without recurrence of ptoms.

hæmoglobin readings were made on a photo- ric colorimeter graduated to register 14·8 g. Hb ml. as 100%. Estimations of the erythrocyte- entation rate (E.S.R.) were made with Westergren s, using Wintrobe's dry potassium and ammonium ate mixture as an anticoagulant.

rnal-marrow biopsies were performed in 4 cases n at random, and all showed a normal active marrow. ric analysis, performed in 8 unselected cases, showed thin normal limits, 2 hyperchlorhydric, and 4 chlorhydric.

RESULTS

16 of the 23 cases a satisfactory rise in the Hb followed the administration of intravenous iron e II).

ter a control period on iron by mouth the average level rose from 70·7 to 72·1%. A month after g. of ferrivenin had been given, the average Hb was 87·5% (fig. 1). The highest average level 95·4%, which was attained in one to six months the last injection. The average Hb level in the observations was 92·5%.

7 cases the response to 1·05 g. of ferrivenin was very . After a month's iron by mouth the average level rose from 71·6 to 72·6%. A month after venin treatment the average Hb level rose from to 77·1%. The average Hb level in the final rvations was 76·5%.

2 of the cases with poor response a second course ·05 g. was given with a slight rise in Hb level, but was not maintained (table II).

se 18 was a very active phase with well-marked articular ction.

se 19 was a confirmed vegetarian of 40 years' standing.

se 21 was bleeding from the intestinal tract, the cause s undiagnosed.

se 23 had bronchiectasis and widespread low-grade mmatory lymphadenopathy.

he E.S.R. in the group responding well to intravenous was initially low and tended to fall, whereas in the up not responding the initial E.S.R. was high and remained raised throughout the period of observation (fig. 2).

DISCUSSION

It appears that the intravenous administration of iron is worth a trial in all cases of hypochromic anæmia associated with rheumatoid arthritis which do not respond satisfactorily to iron by mouth. With ferrivenin, in daily doses not exceeding 200 mg., toxic effects were insignificant in the present series. In several cases there was a delay of two to three months before the Hb level began to rise appreciably: so it is suggested that a second course should not be given for at least three months. In the cases with a good initial response no further iron has been given by any route, but experience may show that where the Hb does not reach 90%, or where it subsequently falls below this level, a second course should be given.

We suggest that cases which respond poorly should receive a second, and if necessary a third, course. Slack and Wilkinson observe "that in chronic infection there is a greatly increased demand for iron by the cell systems of the body and that very large amounts of iron must be provided to enable the bone-marrow to obtain sufficient for its purposes and to maintain a normal plasma-iron level."

It is noteworthy that in the cases which responded poorly the average level of the E.S.R. on admission was high and remained high, in contrast to the cases with good response where the average level of the E.S.R. was low and fell lower after treatment.

SUMMARY

Ferrivenin was used in 23 cases of rheumatoid arthritis with iron-deficiency anæmia which did not respond to a month's treatment with iron by mouth in the form of fersolate gr. 3–6 thrice daily.

Of these 23, 16 responded well and 7 (including 2 when a second course was given) poorly.

LEAD POISONING IN AN INFANT FROM LEAD NIPPLE-SHIELDS

ASSOCIATION WITH RICKETS

I. GORDON — T. P. WHITEHEAD
M.B.Rand, M.R.C.P.E., D.C.H. — A.R.I.C.
HOUSE-PHYSICIAN — BIOCHEMIST
QUEEN ELIZABETH HOSPITAL FOR CHILDREN, LONDON

AMERICAN workers have emphasised that, unless we bear lead poisoning in mind, lead encephalopathy in young children is likely to be missed. Lead encephalopathy in nursing infants was first described in a Japanese monograph in 1784 (cited by Kato 1932) as "meningitis of unknown ætiology"; many years later Japanese workers demonstrated that this meningitis was in fact lead encephalopathy. We describe here a case of lead encephalopathy in a breast-fed infant whose mother had used lead nipple-shields, and it seems likely that similar cases are escaping recognition.

SOURCES OF LEAD POISONING

Sources of lead poisoning in nursing infants are many and various. Le Grand and Winter (cited by Dufour-Labastide 1902) described two authentic cases in newborn infants whose mothers had been exposed to lead during a shallow crater was seen high on the posterior wall. A vessel in the base was plugged with clot.

As the result of these experiences, we in this unit feel that in such circumstances a high partial gastrectomy is the correct procedure. It may be urged that resection is a serious step to take when an ulcer is not proven. In the absence of a gross infiltrating lesion, however, *it can be carried through expeditiously, and in nine cases out of ten trouble-free recovery will follow.*

I would like to thank Mr. W. J. Ferguson for allowing me to take part in the treatment of these cases and for much stimulating advice.

INTRAVENOUS IRON IN HYPOCHROMIC ANÆMIA

ASSOCIATED WITH RHEUMATOID ARTHRITIS

R. J. G. SINCLAIR
M.R.C.P.E.
ASSISTANT PHYSICIAN, RHEUMATIC UNIT, NORTHERN GENERAL HOSPITAL, EDINBURGH

J. J. R. DUTHIE
M.B. Aberd., M.R.C.P.E.
LECTURER IN RHEUMATIC DISEASES, DEPARTMENT OF MEDICINE, UNIVERSITY OF EDINBURGH

THE effect on iron-deficiency anæmia of administering iron intravenously has been studied by Slack and Wilkinson (1949), who tested *two preparations:* (1) an iron-sucrose compound of pH 10·5; and (2) a proprietary preparation, 'Ferrivenin' (Benger). They noted no difference between these preparations in tolerance or response; the initial response was good in 57 of their whole series of 60 cases. The dosage recommended was 200 mg. daily or twice daily. One patient with rheumatoid arthritis received altogether 2550 mg. of iron in three separate courses before a satisfactory response was achieved.

TABLE I—HÆMOGLOBIN LEVELS IN 100 CASES OF RHEU ARTHRITIS, ON ADMISSION AND DISCHARGE

Distribution of patients	Hæmoglobin %			
	<60	61–70	71–80	81–90
On admission ..	1	6	19	28
On discharge ..	Nil	4	8	16

Govan and Scott (1949) used ferrivenin for the ment of 25 cases of anæmia associated with pregnanc dosage was 30 mg. on the first day, 60 mg. on the day, 100 mg. for five days, and then 100 mg. on all days. The hæmoglobin rose rapidly, the increase first week averaging 8%. They calculated th increase the hæmoglobin by 1% these cases re 40 mg. of elemental iron, compared with 24·5 mg. in Slack and Wilkinson's cases unassociated with nancy. Other writers (Cohen 1948, Mitchell French 1949) confirm the efficacy and low toxic ferrivenin. Nissim and Robson (1949) have pr an iron-sucrose compound which they claim is les than ferrivenin; in their experience 300 mg. or can be injected intravenously in a single dose w causing toxic reactions.

GENERAL RÉGIME

Table I shows the hæmoglobin levels on admissi discharge from hospital of 100 consecutive ca rheumatoid arthritis. The average stay in hospit six weeks, *and all patients* were on the same régime, which included full diet and vitamin concen with extra proteins if necessary. Patients with a globin below 80% were given iron by mouth in th of 'Fersolate' gr. 3, rising to gr. 6, thrice daily th *out their stay. On this régime* the hæmoglobin re below 80% in only 12% of cases. It was deci investigate the effect of intravenous iron in cases did not respond to oral iron. The results in 23 are reported here.

TABLE II—EFFECT OF FERRIVENIN ON 23 CASES OF RHEUMATOID ARTHRITIS WITH HYPOCHROMIC ANÆMIA, RESPONSE IN CASES 1–16 AND FAILURE IN CASES 17–23

Case no.	Age (yr.) and sex	Duration of symptoms (yr.)	Hæmoglobin %					E.S.R. (mm. in 1st hr.)				Gastric acidity	S n

* Intravenous iron administered without the initial period on iron by mouth.
† Two courses of intravenous iron.

ng of the ribs and broadening of the lower end of the s, but no craniotabes. The heart and lungs were al, and the blood-pressure was 88/50 mm. Hg. The extended two finger-breadths below the right costal n.

mbar puncture was done two hours after admission. C.S.F. was xanthochromic and contained 18 cells per (1 polymorph and 17 lymphocytes); protein 150 mg., 62 mg., and chlorides 720 mg. per 100 ml. The Nonne- test for globulin was positive, and the Pandy test ly positive. No tubercle bacilli were seen in a direct

ese findings tended to exclude tuberculous meningitis; other cause for the convulsions was sought, and it was elicited from the mother that she had been using lead e-shields continuously since the birth of the baby, ut cleaning her nipples before each feed. She was hy and well-nourished, without any signs or symptoms d poisoning.

ood examination of the baby showed red cells 3,300,000 mm., Hb 56% (Haldane), colour-index 0·85, and white 13,200 per c.mm. (polymorphs 18%, eosinophils 2%, phils 1%, lymphocytes 78%, monocytes 1%). The red showed moderate hypochromia; 2% were stippled cells, 12·6% reticulocytes. There was one normoblast per white cells.

ood-chemistry: serum-calcium 10·7 mg., serum-inorganic phorus 3·2 mg., serum-alkaline phosphatase 32 units, and d-urea 20 mg. per 100 ml. A blood-culture was negative.

ine contained a faint trace of protein and three pus cells high-power field.

ogress and Treatment.—On April 18 the infant was still iting and constipated. His anterior fontanelle was tense pulsating. A subdural tap was done, 2 ml. of fluid was ved from the left side, and 1 ml. from the right. This was xanthochromatic and similar in all respects to the . obtained by lumbar puncture. Further lumbar punc- s were done on April 19, 20, and 21, and 15, 30, and 20 ml. S.F. was removed. The indications for lumbar puncture a tense fontanelle, vomiting, and increased squint. ecimen of C.S.F. examined on May 4 was normal. From l 21 the infant steadily gained weight, though from l 17 to April 23 his stools were green but not loose or uent.

n assay of the amount of lead in the blood on April 23 days after admission) showed 1·9 µg. of lead per g. of d, whereas in the blood of a control infant of the same there was no lead. No lead was found on polarographic ysis of a seven-day specimen of urine on April 30.

loral hydrate gr. 2 was given four-hourly for the con- ions, and the infant was taken off the breast and put on cream National dried milk and vitamin D 4500 I.U .

n discharge on May 16, 1949, the infant weighed 14 lb. 5 oz.

ollow-up.—Three months later the infant showed satis- ory progress, and seemed to be normally intelligent. All clinical signs of rickets had also improved.

adiologist's Report (Dr. C. J. C. G. Hodson).—On admission utine film of the chest showed the unusual combination of e bone and florid rachitic changes. So the skeleton was ographed daily. After only six days' treatment with I.U. of vitamin D daily the bones were stout and within nal limits as regards maturity. The usual absence of p definition between cortex and medulla found in advanced ets was present, with well-marked subperiosteal new bone ation along the concave curves of the tibiæ. The hyses generally were much splayed, and the lower ends he tibiæ showed the usual varus deformity. The juxta- hyseal new bone was ragged, irregularly "calcified," and h denser than is usually found in untreated rickets of this rity. The bone trabeculæ in the shafts were also more que than is usual in such cases. The skull showed a big rior fontanelle and an early beaten-copper appearance ch is uncommon at this age and might again be an ession of increased bone density. The dentition appeared mal. There was thus no doubt that a severe rachitic nge was present, but combined with this was an increased sity of mineralised bone throughout the skeleton, which presumably due to the deposition of a salt of a higher mic number than calcium.

The next series of films (May 2) showed a considerable change. The newly mineralised tissue adjacent to the epiphyses was extraordinarily dense and showed a rapid response to treatment. This was particularly well seen in the anterior ends of the ribs and lower femoral epiphyses. In the later films this dense new bone was very well seen as dense bands bordering both the diaphyseal and epiphyseal sides of the epiphyseal lines, and in the subperiosteal new bone. In July the bones had almost returned to normal except for their widened ends, but one or two dense lines remained parallel to the epiphyses, and the juxta-epiphyseal layers were still much denser than normal. The process can be summed up as representing a normal good response to anti-rachitic treatment, but with the deposition of a salt of high atomic weight in the bone thus formed.

ABSORPTION OF LEAD FROM NIPPLE-SHIELDS

There are several routes by which lead might have been absorbed by the infant from nipple-shields worn by the mother.

(1) *Ingestion of Metallic Lead from Deposit on the Mother's Nipple.*—Rubbing of the shields with the finger, using comparatively light pressure, removed finely divided lead. This was demonstrated not only in new shields but also in shields that had been worn for several months. The lead deposited was difficult to remove entirely from the finger even by vigorous rubbing with moist gauze. Thus gentle cleaning of the nipple just before a feed may not completely remove all the deposit of lead, and this may be absorbed by the infant.

(2) *Ingestion of a Deposit of Lead Salts on the Nipple.*—Lead may be dissolved from the shields by the mother's milk, which collects inside the shield, particularly after it has been acted on by acid-producing bacteria. The following experiment demonstrated that this was possible. A new clean nipple-shield was partly immersed in about 20 ml. of breast-milk inoculated with *Bact. coli* and was kept for forty-eight hours at 37°C. About a third of the total surface of the shield was in contact with the milk. After incubation the milk was poured off, and the total lead content of this milk, determined by polarography, was 0·74 mg. Shields which had been in use for some time had a white deposit on the inner surface; when this was disturbed with a soft swab, using minimal pressure, and then washed off the shield with water, lead could readily be detected qualitatively in the washings.

(3) *Absorption of Lead through Mucosa of the Nipple, and Excretion of it in the Breast-milk.*—This is possible but was not investigated. It has been reported that a mother who had used lead nipple-shields continued to excrete lead in her milk for over a week after the shields had been discarded (Holt and Howland 1940).

COMPOSITION OF SHIELDS

Three pairs of metallic shields obtained from different sources contained a very high proportion of lead. It is believed that a tin lead alloy is sometimes used, but a full analysis of the metals present was not made.

DISCUSSION

Florid rickets in a breast-fed infant of normal birth weight is rare in this country today. Though the present infant had not received cod-liver oil compound or other rich source of vitamin D he had been out daily during the winter and spring. During pregnancy and lactation his mother had received an ordinary full diet, which should have provided a considerable degree of protection. The infant's response to vitamin D excluded a vitamin-resistant rickets, the normal urinary findings and blood-urea level excluded a renal cause, and there was no evidence of cœliac disease. It was thought that the lead poisoning might have been a factor in causing pregnancy. Dufour-Labastide (1902) recorded several cases of poisoning in infants due to secretion of lead in the breast-milk of mothers poisoned by skin cosmetics and hair-dyes. Other sources are lead in face powder used by the mother and in ointment applied to the breast (Holt 1923, Vahlquist and Sälde 1943); feeding-bottles made of glass containing lead, and feeding-bottle stoppers made of metallic lead or of rubber containing lead (Dufour-Labastide 1902); lead plasters and lead dusting-powders applied to the infant's skin (Freedman and Stephenson, cited by Dufour-Labastide 1902); printers' lead type swallowed by the infant (Variot and Remy 1894); and fumes inhaled from burning battery cases (Williams et al. 1933). Lead poisoning from nipple-shields used by the mother seems to have been described first by Cadman in Yorkshire in 1902, and then by Wilcox and Caffey (1926) and Rapaport and Kenney (1939) in America.

FACTORS INFLUENCING DEVELOPMENT OF CHRONIC LEAD POISONING IN CHILDREN EXPOSED TO LEAD

Various factors influencing the development of lead poisoning have been discussed in previous case-reports.

Age.—Infants and children show particular susceptibility to lead poisoning. In a group of 40 cases of lead poisoning in Boston due to the burning of storage batteries, only 2 of the patients were adults, in spite of the fact that children and adults alike were exposed to the fumes (Williams et al. 1933).

Duration of Exposure.

Idiosyncrasy.

Season.—It has often been observed that lead encephalopathy is more frequent in the late spring months. Blackman (1937) thought this was due to a rise in the environmental temperature, but Rapaport and Rubin (1941) suggested that sunlight, by producing vitamin D, probably increased the amount of lead absorbed from the gastro-intestinal tract during exposure to sources of lead. The photosensitising action of sunlight on porphyrins, which are increased in lead poisoning, may play a minor rôle in contributing to the severity of plumbism; this possibility has been supported by experiments on animals (Rapaport and Rubin 1941).

Diet.—Kato (1932) stated that lead poisoning is more common in breast-fed infants than in artificially fed infants. This he ascribed to cows' milk having a higher content of calcium than breast-milk. Another possible explanation might be more frequent exposure of breast-fed infants to sources of lead.

SYMPTOMS AND SIGNS OF CHRONIC LEAD POISONING IN INFANTS

The infant with lead poisoning is generally taken to the doctor because of signs of encephalopathy. Common signs are fretfulness, irritability, sleeplessness, convulsions, vomiting, a tense fontanelle, and opisthotonos. Ocular changes, such as papillœdema, optic atrophy, and *optic neuritis may develop. Peripheral neuritis* in infants is very rare. The infant may have slight pyrexia with a temperature range of 98–101°F. Anorexia is common and, if severe, may lead to failure to gain weight and to emaciation. Other clinical features may be bleeding gums, foul breath, and a dark discoloration of the teeth or tongue. A lead line in the gums is rarely seen. Pallor is usually present early and is due to contraction of the skin capillaries; later a true anæmia develops. There may be a rapid pulse and mild diarrhœa, with dark-green stools; this colour is thought to result from the interaction of hydrogen sulphide, lead, and bile in the bowel.

LABORATORY INVESTIGATIONS

The blood shows a moderate anæmia, punc basophilia, and reticulocytosis. Other changes n include Cabot's rings, normoblasts, and a sl leucocytosis with a normal differential count.

The cerebrospinal fluid (C.S.F.) is under pressure; may be clear or xanthochromic, and may form a pel on standing. There is an increase of protein, and th may be a slight increase of the cell-count (10–25 c.mm.) with lymphocytes predominating.

Biochemical findings which may help in diagnosis lead in the urine, an increased level of lead in the bloo and lead in the hair and nails.

Radiography of the long bones in affected inf usually shows a characteristic dense line or band at epiphyses (Park et al. 1931).

PROGNOSIS AND SEQUELÆ

The prognosis of lead poisoning in infancy is extrem bad. Holt (cited by Ford 1944) reported that 13 of infants with chronic lead poisoning died within a sh period; of the 7 survivors only 1 was restored to norm mental and physical health; the other 6 were left wi mental defect or other neurological lesions. In a ser of cases reported by Kawamura (cited by Kato 19 there was a mortality-rate of 50% and complete recov in only 10%. Levinson and Zeldes (1939) reported th of 26 infants with lead poisoning, 5 died (4 in the ac stage, and 1 a week later); of the 21 survivors 9 w followed for from 4 months to $3^{1}/_{4}$ years; 3 remain in good health; 2 had frequent headaches (1 of th had partial optic atrophy); 1 had frequent abdom pains; 1 was blind, mute, and unable to walk; and had recurrent headaches and were mentally retard Other sequelæ, such as hemiplegia and bilateral weakn of the limbs, were described by Ford (1944).

CASE-RECORD

A male infant, aged 6 months, weighing 13 lb. 2 oz, admitted to the Queen Elizabeth Hospital for Children April 14, 1949. He had been wholly breast-fed until a days before, and had never been given cod-liver oil or ora juice, but had been out of doors daily during the wi months. He was admitted as a possible case of tubercul meningitis. He had had irregular bouts of vomiting du the previous fortnight and convulsions in the previous days. During the preceding month the mother had note slight change in his temperament; he smiled less and t less note of his surroundings.

Past History and Family History.—He had been b weighing 6 lb. 4 oz. after a normal labour. He had no hist of other illness or of head injury. His parents were said be quite well. An aunt of his mother's had died tuberculosis but had never been in contact with him, and mother's brother, aged 16, was being "watched" tuberculosis.

Maternal Diet.—During pregnancy and lactation the mot had had her full rations. She used to sit in the sun whene possible but took no iron or vitamin preparations.

On admission the infant had an attack in which he vomit "went waxy-white, and developed a squint in the right e Immediately after this there was definite *twitching* of right side of the face and right arm. Soon after admis he had a generalised convulsion, and his eyes showed conju deviation to the left and upwards. After the convuls nystagmus in both lateral directions was present, and infant was lethargic though conscious.

His general nutrition was good, and temperature norm but he was pale. The anterior fontanelle was bulging, ten and pulsating; there was possibly some scaphocephaly a slight separation of the sutures. Veins in the left tempo region were prominent and congested. All reflexes w present and equal. Chvostek's and Trousseau's signs w negative. The ocular fundi were normal. There was internal squint of the right eye. There was well-mark rork had been concerned solely with book-keeping and red no hazard of lead absorption. Her sister, who lived same house, had a urinary lead level within normal limits ormal blood. The urinary lead level and blood of another it with a similar skin condition in the ward at the same were also normal. The patient's blood-urea level was g. per 100 ml. Wassermann and Kahn reactions were ive.

atment.—It was decided to investigate and treat the nt as a case of chronic lead poisoning.

ad dressings were removed, and no further lead was ed. "De-leading" treatment was given. A low-calcium was started, and ammonium chloride gr. 75 was given by mouth. Intramuscular 'Parathormone' 50 units was given for five days. During this treatment daily led and reticulocyte counts were made. Daily 24-hour mens of urine were collected in acid-washed 'Pyrex' iners for the estimation of urinary lead. Blood-calcium were determined on three occasions (Kramer and ll's (1921, 1923) method as modified by Trevan and bridge (1926)). The patient was kept under careful vation during the administration of the parathyroid ct. These injections were discontinued on the fifth day g to a complaint of paræsthesiæ in arms and legs and mbness in the right thumb and forefinger. Clinically no tive abnormality of the central nervous system was d.

ter the fifth day of treatment the level of urinary lead n to fall very rapidly without any previous significant fig. 1). The level of 0·44 mg. per litre was attained on the the patient complained of paræsthesiæ in her limbs.

matological Findings.—On Dec. 7, 1948, examination of blood showed Hb 9·47 g. per 100 ml. (64% Haldane), cells 4,620,000 per c.mm., colour-index 0 69, and white 5600 per c.mm. (neutrophils 50%, eosinophils 11%, phils 1%, lymphocytes 37%, monocytes 1%); hæmato-reading 35%; erythrocyte-sedimentation rate 4 mm. in ur (Wintrobe); mean corpuscular volume 78 c.μ; mean uscular hæmoglobin concentration 29%. One normoblast C) was found per 100 white cells. The red cells showed chromia, with slight anisocytosis and poikilocytosis. ctate basophilia was well-marked; this had not been rved in a blood examination some months before. These led cells formed 3% of the red cells—i.e., 30,000 per 0,000 red cells—a grossly abnormal figure. The stippling coarse, granular, and similar to that seen in a proved case oisoning in a lead worker under observation at the same . Lane (1931) states that, in a lead worker, a count of 3000 led cells per 1,000,000 red cells is of no pathological ficance but merely suggests that the person follows that pation; higher counts are definitely pathological, cially if the stippling is coarse. McCord et al. (1935) ider that more than 3000 stippled cells per 1,000,000 cells is usually evidence of lead intoxication. The stippled it in our patient, who had had no known contact with apart from lead in dressings, was therefore very ificant.

derocytes were looked for by the prussian-blue method, none was found. Further, staining with basic fuchsin as a nuclear stain and counterstaining with light green did not show any stippling. This indicated that we were dealing with punctate basophilia and not with nuclear remnants—e.g., Howell-Jolly bodies.

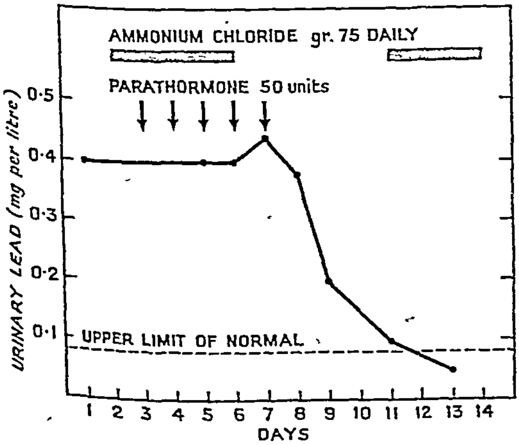

Fig. 1—Urinary excretion of lead.

Assuming that stippling is, with polychromasia, a manifestation of reticulation (Whitby and Britton 1933), we made daily reticulocyte and stippled counts during the treatment. The results are shown in fig. 2. It was noted that the stippled pattern tended to become finer as the count fell during treatment. The roughly parallel fall seemed to indicate that the toxic agent was being eliminated. Such a result might be expected in a case of lead intoxication responding to treatment.

Progress.—Under the régime of treatment outlined above certain symptoms showed striking improvement: the abdominal colic disappeared; the bowels became regular; the appetite returned to normal; nausea and vomiting were greatly improved; and the patient's mental outlook became better. Insomnia was still troublesome, but less so than before treatment. Headaches were now only occasional.

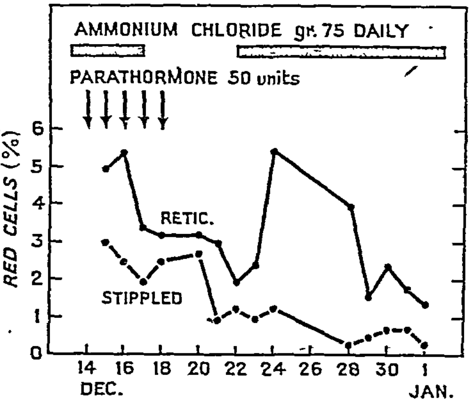

Fig. 2—Reticulocyte and stippled counts.

DISCUSSION

Lead poisoning by absorption of lead through the skin is rare. In the present case one must assume that lead was absorbed through a damaged skin. Teleky cited by Heffter and Heubner 1934) estimates that 1 mg. of lead ingested daily for some months will produce poisoning. Sollmann (1922) holds that daily ingestion of 10–20 mg. of lead for several weeks will lead to clinical plumbism. In our case it is estimated that 1400 mg. of inorganic lead was applied daily for sixteen weeks.

Cutaneous absorption of lead has recently been demonstrated in rats by Laug and Kuntze (1948). Volatile tetra-ethyl lead penetrated the skin in twenty-four hours with relative ease, whereas non-volatile lead compounds did so in very small quantities. Mechanical injury to the skin increased the absorption of both volatile and non-volatile lead compounds. Though these experiments on rats may not apply to the intact human skin, possibly a damaged human skin in contact with lead for a long time will permit the absorption of a dangerous quantity of lead.

We felt justified in trying to de-lead this patient because no large storage of lead in the body was anticipated. Belknap (1935) de-leads mild cases in ambulant patients under close supervision, but "most authorities feel that the de-leading should be carried out only in the hospital and with adequate laboratory checks" (Johnstone 1941).

The insignificant rise in the urinary lead level before the return to a normal figure can be explained by (1) a relatively small excess of lead in the body, with little or no storage in the bones, and (2) excretion of the bulk of the lead in the fæces. Aliavdin and Peregood (1936) have shown that the level of lead in the duodenal juice the rickets. If the lead precipitated the phosphorus of the breast-milk in the gut, the infant might have suffered from phosphorus deficiency, but the quantity of lead swallowed would have to be very large to allow of such a mechanism.

We have found only one definite published case of lead poisoning associated with rickets; this was due to lead acetate applied to the mother's breast (Holt 1923). Another case with possible rickets was published by Norton (1922), who described the baby as "having an asymmetrical head with frontal and parietal bossing, more marked on the right than the left side." These cases, however, occurred at a time when rickets was much more common. Many cases of lead poisoning have been described in the Japanese series (see Kato 1932), but no reference is made to any association with rickets.

Wilcox and Caffey (1926) and Rapaport and Kenney (1939) described cases of lead poisoning due to lead nipple-shields. This method of treating the nipples of a lactating mother was thought by many pædiatricians to be obsolete, but lead nipple-shields are still quite widely used in maternity homes and hospitals. Lead nipple-shields have been advocated by DeLee (1933), Edgar (1926), Schumann (1936), and Naish (1948) for the treatment of diseased nipples, and the manufacturers emphasise their complete harmlessness to the infant.

Wilcox and Caffey (1926) state: "The lead nipple-shield is a definite source of danger to the nursing infant if used for longer periods than 2–3 weeks"; but in our view these shields should not be used in any circumstances whatsoever, since the risk of lead poisoning, with its high mortality, is too serious to take. Shields made of plastic, or other non-poisonous substances, will be safe and equally effective.

SUMMARY

A case of lead poisoning in an infant whose mother had used lead nipple-shields during lactation is described.

The lead poisoning was associated with rickets.

The serious prognosis and sequelæ of lead poisoning in infants are emphasised.

The probable mode of absorption of the lead from the nipples by the infant is discussed.

In view of the risk of poisoning, lead nipple-shields should never be used.

We wish to thank Dr. H. M. M. Mackay for her help, guidance, and permission to publish the case; Dr. Donald Hunter and Dr. B. Levin for their advice and help; and the staff of the X-ray department and the nurses for their invaluable assistance.

LEAD POISONING BY CUTANEOUS ABSORPTION FROM LEAD DRESSIN

C. COTTON KENNEDY
M.A., B.M. Oxfd
ASSISTANT CLINICAL PATHOLOGIST

H. AUDREY LYNAS
M.B. Belf.
HOUSE-PHYSICIAN, DEPARTMENT OF DERMATO

ROYAL VICTORIA HOSPITAL, BELFAST

LEAD poisoning from the absorption of non-vol lead compounds through the skin is very rare. In 1 Tanquerel des Planches referred to poisoning thro the application of lead-containing lotions and ointm to ulcers, sores, and inflamed skin; and more rece poisoning from cosmetic preparations has been repo by Woltman (1922) and Soewarno (1930). Conway (1 has written of cases of poisoning in babies in the Ori in these cases large quantities of white lead had b applied to the mothers' faces, necks, and breasts, to the infants themselves. Lead poisoning from dye has been recorded by Valdiquié and Planque (1 in France, Smith (1932) in America, and Busacca (1 and Pichezzi (1935) in Italy. Bartleman and Du (1936) published the case of an actress who develop chronic lead poisoning from theatrical grease-pa Matz (1942) described poisoning in a child caused plaster of lead oleate (diachylon) applied to the ski he found only three cases previously recorded due this substance.

CASE-RECORD

Miss A, aged 46, a clerk, was admitted to the Royal Victo Hospital, Belfast, in March, 1948, with generalised exfoliat dermatitis of eight months' duration. Apart from m *depression and tiredness there were no subjective* symptom General treatment in hospital took the form of a supplement high-protein diet and suitable mild sedation. Local treatm consisted in the application of various dressings to the enti body surface. These dressings included lead in the form 2% liq. plumbi subacet. fort. *B.P.*; lotio calamin. co.; cremor zinci, *N.W.F.*; and lotio pic. et plumb. (*Bel Hospitals' Pharmacopœia*).* These lead dressings were appl intermittently from May to December, during which perio lead in some form or other was in contact with th skin for about sixteen weeks. Mild lead intoxicatio resulted.

In November, 1948, seven months after admission, the sk showed definite improvement, but the patient complain of new symptoms, including nausea and vomiting, colic abdominal pain, constipation, nervousness, headache, slee lessness, and loss of appetite. The pain was severe, circu umbilical (radiating towards the epigastrium), inconstan colicky, and most severe after meals, when the patient of vomited a little. Alkalis did not give relief. Constipation w severe, and enemas were given almost daily in the fortnig preceding the onset of the pain. The headache was continuou frontal, and different from any headache the patient had ev had before.

On examination the patient was very thin, with pale fa and conjunctiva, and an ashen hue below the eyes. Her who body was covered with exfoliative dermatitis. There was significant abnormality of heart, lungs, or central nervo system. The liver extended to a finger-breadth below t costal margin; no abdominal tenderness was elicited. Slig œdema of the ankles was present. *The menses* had cea some years previously. The patient was edentulous. H blood-pressure was 145/75.

Blood Examination.—In early December, 1948, there w widespread stippling of the red cells (see below). This puncta basophilia was so conspicuous that urinary lead was estimate The lead level in a 24-hour specimen of urine was determin by the dithizone method of Ross and Lucas (1935) and Keh et al. (1935). Kehoe estimates 0·04 mg. per litre as a me normal (Johnstone 1941), and a reading as high as 0·1 m per litre is considered by most authorities the upper limit normal. Urinary lead in the present case was 0·4 mg. per litr which is four times the accepted upper limit of normal. Th patient had been previously employed as a clerk in a laundr

s (2 mega-units) in single intramuscular doses without ctable toxic effect. In our patients receiving peni- therapy there was the usual small proportion of ersensitivity phenomena.

METHOD OF ASSAY

he technique used was a modification of the capillary- serial-dilution method described by Fleming and th (1947). In this method a penicillin sensitive hæmo- streptococcus actively ferments glucose with the luction of acid, which is detected with phenol red. oughout the investigation the organism used remained sensitive to standard solutions of penicillin $^1/_{32}$ unit ml. When medium and C.S.F. were used in equal imes, the minimal detectable level of penicillin was $^1/_{15}$ unit per ml. To detect lower levels a five-times entrated medium was used, enabling penicillin levels 037 unit per ml. to be detected. A specimen could be reported as containing one of the following ls of penicillin: up to 0·037 unit per ml.; 0 037–0 062 unit per ml.; 0 062–0·125 unit per ml.; 0·125–0·25 unit per ml.; or 0·25–0·5 unit per ml. For a while it was impossible to put up the most sensitive tube containing the concentrated medium; for this reason some values of 0–0 062 unit per ml. were reported.

Several control studies were made to assess the reliability of the method. Of 15 specimens of C.S.F. known to be free from penicillin and submitted for assay none gave a false positive. Samples of C.S.F. containing known levels of standard penicillin were assayed in duplicate. Correct reports were returned in 11 out of 14 assays; the largest error was in reporting a specimen containing 0·15 unit per ml. as containing 0·06–0·125 unit per ml. Finally, C.S.F. was obtained from 11 patients by ventricular puncture six hours after large intramuscular doses of penicillin (0 5–2 mega-units). Each sample was assayed nine times, and each assay included a penicillinase control. None of the 99 control tubes gave a false positive (lack of growth of the organism in the presence of penicillinase). The results of these assays are shown in table I.

LE III—PATIENTS WITH NEUROSYPHILIS WHO RECEIVED EITHER 1, 2, OR 3 FIVE-DAY COURSES OF PENICILLIN (COURSE A, B, AND C) AT ABOUT MONTHLY INTERVALS

	Age (yr.)	Sex	C.S.F. before treatment			C S.F.-penicillin level

Dosage 0 5 mega-unit intramuscularly every four hours. Courses A and C consisted of penicillin alone. During course B 6 of the patients e having B.T. malarial rigors above 103°F. and 2 of the patients were receiving 4 g. of caronamide every four hours, starting four s before penicillin was started (specimens marked M and C respectively in the column "Course B"). Two lumbar punctures performed during each course, twelve hours and eighty-four hours after the course started.

may be 10–30 times as high as in the urine. Experiments on animals have shown that the higher lead level in the duodenum is due to the presence of bile (Behrens, B. and Baumann, A. cited by Cantarow and Trumper 1944). In addition to excretion of lead in the bile, the large intestine appears to be the chief route by which lead leaves the body, which is also the case with other heavy metals. Determination of the quantity of lead in the fæces is of little practical value, and no estimations were made in the present case.

Unfortunately only three blood-calcium estimations were made during treatment. The day after the second injection of parathormone the blood-calcium level was 9 mg. per 100 ml. After the fourth injection it was 8 mg., and two days after the fifth and last injection it was 7·6 mg. We are at a loss to explain this fall in the blood-calcium. However, failure of the blood-calcium level to rise above the normal figure in similar circumstances is not without precedent. Hunter and Aub (1927) made observations on the blood of six patients with lead poisoning treated with parathyroid extract. In one of these cases there was no rise in blood-calcium after treatment for fifteen days with an average daily dose of 65 units, but the total output of calcium was increased. This illustrates that increased excretion of calcium does not depend on a raised blood-calcium level.

We feel that the evidence for lead poisoning in our patient is strong. The damaged skin over the whole body could not have formed an efficient barrier to the absorption of lead from the long-applied lead dressings. The symptoms and signs at the end of this period could have been due to mild lead intoxication. The striking punctate basophilia is very strong evidence of plumbism. This hæmatological finding is common in certain other conditions, but only in lead poisoning does one find the coarse pattern and high stippled count noted in the present case. The initial count of 30,000 stippled cells per 1,000,000 red cells is ten times what some authorities regard as the "danger line" figure in lead workers. With a figure of 3000 stippled cells per 1,000,000 red cells the worker is removed temporarily from the lead hazard. The first urinary lead figure was four times the upper limit of normal. Finally, when lead was eliminated, there was a decided clinical improvement, a return to normal of the urine, and the disappearance of punctate basophilia.

We emphasise the danger of applying lead dressings for a long period to a damaged skin; also the protean character of lead poisoning, and in mild cases the lack of "classical" signs and symptoms of the older textbooks.

SUMMARY

A case of generalised exfoliative dermatitis showing mild lead intoxication is reported. Intoxication followed the application of lead dressings (chiefly liq. plumbi subacet. fort. *B.P.*) to the whole body surface for about sixteen weeks.

The urinary lead level was 0·4 mg. per litre (four times the upper limit of normal).

Punctate basophilia was striking; the first stippled count was 3%, representing 30,000 stippled cells per 1,000,000 red cells.

Stippling of the red cells disappeared and the urinary lead returned to within normal limits after removal of the lead dressings and treatment with a low-calcium diet, ammonium chloride by mouth, and injections of parathormone.

The rarity of lead poisoning by cutaneous absorption of non-volatile lead compounds is emphasised. Other cases are cited.

We wish to thank Dr. Ivan H. McCaw for permission to publish this case, and Dr. M. G. Nelson for advice and encouragement.

UNTIL recently the uninflamed blood-cerebrospi fluid (C.S.F.) barrier has been regarded as imperme to penicillin.

Cairns (1947) stated that penicillin given parenterally d not enter the cerebrospinal fluid. Rammelkamp and Ke (1945), Kaplan et al. (1946), Ory et al. (1945), and Neym et al. (1945) all reported negative findings. Walker a Johnson (1946) categorically denied that penicillin can p into the normal ventricular system: they dismiss impor previous positive findings (McDermott and Nelson 19 Schwemlein et al. 1946) on the grounds of abnormaliti e.g., syphilis—in the patients studied, which might incr the permeability of the membrane.

We present here sufficient evidence to show that normal barrier is permeable to penicillin, and that th permeability is increased by organic disease of the centr nervous system, such as neurosyphilis. The negati findings previously reported are, we think, attributa to the small doses used and the difficulty of detec penicillin in low concentration, especially in the C.S.F.

Previous investigators have used specimens of C only from patients undergoing routine treatment w penicillin. In the present investigation penicillin h been administered to patients undergoing routine di nostic lumbar, cisternal, and ventricular puncture. T seemed justifiable so long as toxic symptoms did n develop as a result of the large doses of penicillin. far as we are aware, the dose of penicillin toxic to m has not been determined, but we have given 2,000,0

.S.F. Among these 11 were 2 depressives, 1 psycho- and 1 schizophrenic. The C.S.F.-penicillin levels as follows:

penicillin t per ml.)	0–0·037	0·037–0·062	0·062–0·125	0·125–0·25
specimens	5	7	4	0

e findings in the cases of neurosyphilis are shown in III. Case 55, though not proved to have involve- of the nervous system, has been included in the to show the effects of ‘Caronamide.’ Comparing esults in the first column of penicillin levels with of the group of 17 patients who had had the same ge of penicillin, we see that penicillin is found more often and in larger concentrations in the syphilitics.

e nearest approach to normal controls for the nts with neurosyphilis is provided by patients from group of 17, who underwent lumbar puncture after four-hourly injections of 0·5 mega-unit each. From 17 the 10 were selected who had normal C.S.F. and emonstrable organic disease. Their diagnoses were chopathic personality, 3 schizophrenia, 2 depression, opathic epilepsy, and 1 confusional state, for which rganic cause was found. When we compare the ngs in this group with those from the 10 patients late neurosyphilis (case 55 excluded) after they had the same dosage of penicillin, we obtain the ts shown in table IV.

ABLE IV—COMPARISON OF PERMEABILITY IN NEURO- HILITICS AND A GROUP OF PATIENTS WITH NORMAL C.S.F.

—	C.S.F.-penicillin (unit per ml.)					Mean level (unit per ml.)
	0–0·037	0·037–0·06	0·06–0·125	0·125–0·25	0·25–0·5	
syphilis	1	3	3	1	2	0·14
ols ..	4	5	1	0	0	0 04

is comparison does not bear out the assumption of r et al. (1948) that the barrier permeability of their nts with neurosyphilis was not increased.

nother 4 specimens of C.S.F., from patients under tment for neurosyphilis at Horton Hospital, were ly supplied by Dr. Whelan. The patients had all receiving intramuscular penicillin 0·3 mega-unit y twenty-four hours for ten to twelve days before bar puncture. The samples of C.S.F. were taken shortly re the next injection was due. Of these 4 specimens, ontained 0·037–0·062 unit per ml., and the 4th 2–0·125 unit pér ml.

rum-penicillin levels were measured during the ses of penicillin in 6 of the neurosyphilitic cases for s of 500,000 units. The samples of blood were with- n 1 minute before injection, and 10, 20, 30, 40, 120, and 180 minutes after injection. The peak level –64 units per ml., averaging 22 units per ml., is ined about twenty minutes after injection. The age levels one hour, two hours, three hours, and hours after injection were 5, 2·5 units, 0.5 and 0·4 per ml. respectively.

ase 56 developed glycosuria, albuminuria with granu- casts, and microscopic hæmaturia twenty-four hours r the start of caronamide administration. Caronamide stopped, and the urine became normal over the t four or five days. There were no symptoms.

DISCUSSION

eability in Persons without Disease of Central Nervous tem

he present material contains enough persons without gnisable disease of the central nervous system to w that the normal blood-C.S.F. barrier is permeable penicillin. It includes people who had headaches without demonstrable organic cause, vomiting without involvement of the central nervous system, psychopathic personality, schizophrenia, and depression, who yielded positive findings.

Relation of Permeability to Disease of Central Nervous System

Boger et al. (1948) assayed the penicillin in the C.S.F. in cases of general paralysis of the insane after 5 days' treatment with intramuscular penicillin 0·1 mega-unit three-hourly. Their findings, compared with the present findings after three and a half days at 0·5 mega-unit four-hourly, are shown in table V.

TABLE V—PERCENTAGE OF CASES SHOWING VARIOUS C.S.F.-PENICILLIN LEVELS (UNIT PER ML.)

25 cases of Boger et al. (1948)	0–0·03 48%	0·03–0·06 48%	0·06–0·125 4%	0·125 0
Present 11 cases ..	0–0·037 9%	0·037–0·06 18%	0·06–0·125 45%	0·125 33%

The higher values obtained in the present study are presumably to be explained by the much higher dosage used and the greater severity of the syphilitic process. Boger et al. (1948) state that none of their patients had more than 25 cells per c.mm. in the C.S.F.

It has been seen that the mean C.S.F.-penicillin level in the patients who underwent lumbar puncture was about the same as for those undergoing ventricular puncture. It therefore seems probable that, four hours after the injection, penicillin is distributed fairly evenly throughout the C.S.F.

The similarity of the means for these major groups makes it permissible to group together patients with the same diagnosis, regardless of the site of puncture, whether lumbar or ventricular. It also seems justifiable to disregard the fact that some of the patients received one injection and some three injections before the C.S.F. was sampled. The mean C.S.F.-penicillin levels in the two groups who received lumbar punctures after one and three injections of 0·5 mega-unit were the same.

TABLE VI—RELATIONSHIP BETWEEN C.N.S. PATHOLOGY AND PERMEABILITY TO PENICILLIN

Diagnosis	No. of cases	C.S.F.-penicillin levels					Mean C.S.F.-penicillin level (unit per ml.)	Mean C.S.F.-protein level (mg. per 100 ml.)
		0	+	+ +	+ + +	+ + + +		
Neurologically normal (psychiatric cases, no C.N.S. findings) ..	9	3	5	1	0	0	0·04	12
Idiopathic epilepsy ..	9	4	5	0	0	0	0·04	12
Cerebral glioma ..	14	0	11	3	0	0	0·06	20
Cerebral arteriosclerosis	4	0	1	3	0	0	0·08	40
Neurosyphilis ..	10	1	3	3	1	2	0·14	80

The findings shown in table VI are taken to indicate that those pathological processes which damage vascular tissue, either locally or generally, cause larger amounts of protein and penicillin to appear in the C.S.F. But the parallelism between C.S.F.-protein and C.S.F.-penicillin levels is by no means absolute, as table II shows. Penicillin may enter the C.S.F. through the choroidal plexus. It is equally possible that it enters elsewhere by diffusing through the lining membranes of the C.S.F. system, along the Virchow-Robin spaces, or even via the connexions with the extraneural lymphatic system. The correlation between C.S.F.-penicillin and C.S.F.-protein levels suggests a similar mode of entry for the two substances. The following observation is clear evidence that penicillin penetrates disorganised tissue.

TABLE II—PATIENTS WHO RECEIVED 0·5 MEGA-UNIT OF PENICILLIN INTRAMUSCULARLY 4–6 HOURS BEFORE UNDERGOING VENTRICULAR PUNCTURE

SUMMARY OF FINDINGS (SPECIMEN 63 EXCLUDED)

C.S.F.-penicillin level (unit per ml.)	0–0·06	0–0·07	0·037–0·06	0·06–0·125	0·125–0·25	Total
No. of specimens ..	4	11	23	16	1	55

Estimated mean concentration: 0·057 unit per ml.

It is clear that the chances of a false positive are less than 1 in 100, and that many specimens taining therapeutically significant levels of penicillin be reported as negative. For example, in table I, the from cases 1, 2, and 5 was shown to contain static levels of penicillin, yet of 27 assays 14 gave a negative. This table also shows that, for the C.S.F. which all 9 assays gave positive results, the chances any single estimation being quantitatively incorrect about 1 in 5.

All specimens were transported and kept on ice assayed. Serial assays showed no loss of antibi activity over the greatest period of 48 hours during the specimens might be stored before being assayed.

No visibly bloodstained specimens were used. Micro scopic contamination up to 20,000 red cells per c.m can be neglected ; if the systemic serum-penicillin lev at the time of withdrawal of the C.S.F. is 0·5 unit per the contamination would only add 0·002 unit per to the C.S.F.

CASE-MATERIAL

There were assayed 152 samples of C.S.F. from 1 patients, of whom 97 were undergoing routine diagnos lumbar, cisternal, and ventricular puncture at th Maudsley and Atkinson Morley Hospitals. In additi there were 10 cases diagnosed as late parenchymato neurosyphilis and 1 case of congenital syphilis und treatment at the Maudsley Hospital, and 4 cases general paralysis of the insane being treated at Hort E.M.S. Hospital, Epsom.

RESULTS

The cases have been divided into groups accordin to the site from which the C.S.F. was withdrawn and th dose of penicillin received beforehand. The neurosyph litic cases have been kept separate.

From 55 patients 56 specimens (table II) of ventricul C.S.F. were obtained between four and six hours aft the intramuscular injection of penicillin 0·5 mega-uni Of these patients 40 (73%) had assayable penicillin i the C.S.F. In 6 of these cases the final diagnosis wa idiopathic epilepsy ; 4 of these had penicillin in th C.S.F. Of 13 cases of glioma all showed more than 0·03 unit of penicillin per ml.

Intramuscular penicillin 0·5 mega-unit was given 7 patients four hours before cisternal puncture. In 4 these (57%) penicillin was detected in the C.S.F. Th C.S.F. from the 1 patient who was finally diagnosed free from organic disease contained assayable penicilli

In addition 1 mega-unit was injected intramuscularl into a patient undergoing cisternal encephalography t exclude early presenile dementia. He had previousl received two lumbar punctures ten days apart, four hou after the injection of 0·5 mega-unit, and in neither these samples had penicillin been detected. Fifty minut after the injection of 1 mega-unit his cisternal C.S. contained 0·06–0·125 units of penicillin per ml. The fina diagnosis in this patient was schizophrenia.

Penicillin 0·5 mega-unit was given to 12 patients fou hours before lumbar puncture. Of these, 2 had a increased number of white cells in the C.S.F. Of th remaining 10, 5 (50%) showed assayable penicillin. A the patients in this group had gross lesions, such a prolapsed disc, cord tumour, and head injury. The C.S.F.-penicillin levels were as follows :

C.S.F.-penicillin (unit per ml.)	0–0·6	0–0·4	0·04–0·06	0·06–0·125	0·125–0·2
No. of specimens	1	4	4	2	1

Estimated mean concentration of these specimens = 0·056 un per ml.

Three doses of penicillin 0·5 mega-unit were given to 17 patients twelve, eight, and four hours before lumbar puncture. One of these had meningococcal meningitis; her C.S.F.-penicillin level was more than 2 units per ml. Of the remaining 16 patients 11 (69%) had penicillin in

ssisted in many ways. Messrs. Glaxo Ltd. supplied the n penicillin and standard solutions of penicillin.

ERFORATED PEPTIC ULCER AFTER GASTRO-ENTEROSTOMY

G. GORDON CROWE
F.R.C.S.E., M.B. St. And.
RGEON, CITY GENERAL HOSPITAL, STOKE-ON-TRENT

RFORATION of a peptic ulcer after operation for the of peptic ulcer is a rare occurrence of which I can nly one reported example. Courty and Gaudefroy [1] t a case of peptic ulcer occurring immediately gastrectomy and perforating eighteen days after peration. In the case reported here an existing loric gastric ulcer perforated six days after a o-enterostomy performed for pyloric stenosis.

woman, aged 65, a diabetic, had complained of a dull and a heavy feeling across the epigastrium for eighteen hs, with repeated attacks of vomiting of acid-tasting The vomiting relieved her, but alkalis had no effect e pain, which used to wake her up at night. She gave story of hæmatemesis, but had lost a good deal of weight. *examination* there was obvious loss of weight in her men. She was tender in the epigastrium and had marked gastric succussion. Barium-meal examination ed deformity of the duodenal cap with much delay ptying, the delay evidently being in the first part of duodenum. The radiologist suggested a neoplasm of all-bladder or pancreas. Test-meal showed high free total acidity. Hæmoglobin 82%, red cells 4,060,000 . mm. Colour-index 1·02. The fasting blood-sugar was g. per 100 ml. The diagnosis of pyloric stenosis was and operation was decided upon.

operation (March 14, 1949) through a right paramedian on a huge dilated stomach was found with pyloric sis due to chronic ulceration of the prepyloric region. osterior gastro-enterostomy was performed and the men closed.

stoperative Course.—After operation she had gastric on and intravenous 0·18% (a fifth of isotonic) saline he drip method until the third day when the bowel ds returned. She was sitting out of bed on the third and was making satisfactory progress until the sixth day operation, when she vomited 6 oz. of fluid "like peat r," and collapsed. She complained of no pain and ared to have acute cardiovascular failure. An intra-us drip was started again but she rapidly became semi-tose and pulseless. She had a pleural rub at the left , and had stertorous breathing. It was thought that might have had a pulmonary embolus and heparin was n into the drip. Sixteen hours after collapsing she died.

ecropsy Report.—The surgical wound was quite clean. gs congested. Heart normal in size. Myocardium pale friable. The peritoneal cavity contained a pint of thin n purulent fluid. The stomach was much distended. prepyloric ulcers about 1 cm. in diameter were present, one had perforated. The gastrojejunostomy was patent healthy. The rest of the intestine and the kidneys and reas were normal. The liver was pale, and the gall-der contained a few bilirubin calculi. The cause of death peritonitis from a perforated gastric ulcer.

y thanks are due to Dr. C. Giles for the necropsy rt.

Reviews of Books

The Trend of Scottish Intelligence

The Scottish Council for Research in Education. London: University of London Press. 1949. Pp. xxviii+151. 7s. 6d.

IN the course of their inquiries the Royal Commission on Population were led to give special attention to the possible effects of the known differences in the birth-rate on the trend of national intelligence. The earliest school surveys, made in London as long ago as 1913, indicated a negative correlation between the size of the family and the amount of intelligence as assessed by psychological tests. On the other hand, a repetition of the tests at later periods failed to demonstrate any actual decline, at least of the order suggested by the correlation; and the general opinion of experienced teachers and education officials was that, so far as their memories would carry, the level of ability had remained pretty constant.

In view of this uncertainty, Sir Alexander Carr-Saunders, chairman of the Population Investigation Committee, suggested that one way of securing further evidence might be to repeat the psychological survey carried out by the Scottish research council in 1932. In that year a complete age-group, numbering something like 87,500 children, had been tested; and it was thought that if, as some had argued, the level of intelligence was falling rapidly, the effect should reveal itself after an interval of 15 years.

Accordingly a second survey was undertaken in 1947: and a preliminary account has now been published. The nine chapters of the report have been distributed among 8 contributors, and deal mainly with the details of the tests employed, the administrative arrangements needed for their application, the methods of marking, and a brief analysis of the more important results. As regards the main issue, we are told that, if the figures can be taken as they stand, then there was, during the short period in question, "not only no fall in the average score, but quite a substantial increase." Prof. G. H. Thomson, however, in his preface is inclined to attribute the change to increasing familiarity with psychological tests, and points out that, for this and other reasons, the figures obtained may quite possibly obscure an actual decline. Before any final conclusions are drawn, therefore, we must wait for the more detailed analysis of the data which the council promises, and possibly a third survey undertaken at a longer interval from the first. Meanwhile, the enterprise of the Scottish research council in organising so formidable a task may well encourage education authorities elsewhere to undertake similar school surveys: and the detailed account of the methods finally adopted will show how such schemes may best be planned and how the inevitable difficulties may be overcome.

Prognose und Therapie des Geisteskrankheiten

(2nd ed.) MAX MUELLER, M.D. Stuttgart: Thieme. 1949. Pp. 217. DM. 16.50.

Dr. Max Mueller surprised many who had read his book on psychiatric prognosis and therapy, in which psychotherapy was extolled, by becoming one of the most active proponents of insulin treatment after it had been introduced by Sakel. In the preface to this second edition of his book, he explains that the advent of such physical methods has obliged him to rewrite it throughout, without however attempting to deal more than cursorily with treatment by insulin, convulsions, or leucotomy: he has a separate detailed work on physical treatment ready for publication. Dr. Mueller still holds, however, that the psychopathological point of view is the essential one and that psychotherapy, with its concern for the whole man, cannot be ousted by a mechanical application of physical methods. His book represents the outlook of modern Swiss psychiatry, with the limits imposed on it by isolation during the war: thus in seven pages devoted to the treatment of general paralysis, all that is said of penicillin is in a sentence added to an account of the use of arsenicals, to the effect that "similar favourable results are reported of penicillin also." In the main, however, the book gives a valuable account of

Samples of fluid from three cerebral gliomatous cysts, which contained large amounts of protein, were assayed four to six hours after the injection of penicillin 0·5 mega-unit, when the serum-penicillin level would be about 0·4 unit per ml. These samples contained 8·0 units, 0·5, and 0·5 unit per ml.

That both penicillin and protein in amounts in excess of the normal may reach the C.S.F. by way of such damaged areas seems an obvious inference, for which, however, there is so far no direct proof.

Permeability and Age

The findings suggest that permeability may be increased in the elderly. The tendency is masked by the differences in pathology, but an attempt to allow for this factor to some extent has been made by excluding from the following comparison all those patients with a raised C.S.F.-protein level, including the neurosyphilitics and those who have received 20,000 units three-hourly. The figures in table VII have been changed to percentages for ease of comparison.

TABLE VII—SHOWING INCREASED C.S.F. CONCENTRATIONS IN THE ELDERLY

Age (yr.)	No. of cases	C.S.F.-penicillin level			
		0	+	++	+++
10–49	48	35%	48%	14%	2%
50 or more . .	17	12%	41%	41%	6%

Other Factors

No sex differences were detected, and no correlation between C.S.F.-penicillin level and pressure of C.S.F. The effect of malarial pyrexia on permeability is apparently slight.

The neurosyphilitic patients (cases 49 and 54) showed a decrease in permeability throughout the course of penicillin, presumably concomitant with a decrease in œdema or some other improvement in the function of the barrier membranes during therapy.

It has been previously shown by Boger et al. (1948) that caronamide raises the serum-penicillin and C.S.F.-penicillin-levels resulting from a given dose of penicillin. Cases 55 and 56 show the effect on C.S.F.-penicillin levels.

Optimum Dosage Schemes for Neurosyphilis

We have advanced evidence that penicillin permeates more readily tissue whose vascular structure is damaged. Probably the greater concentrations found in neurosyphilitics results at least in part from the penicillin permeating through the damaged membranes of small blood-vessels more readily than it would through normal tissue. It is known that the spirochætes are to be found in larger numbers alongside vessels and Virchow-Robin spaces in such damaged areas. This probably explains the efficiency of even rather small doses in the treatment of neurosyphilis. However, it is also probable that at all stages of neurosyphilis some spirochætes will be found in comparatively undamaged areas. To deal with these organisms, doses which penetrate normal tissue would be required. Now, if penicillin appears in the C.S.F., one cannot say that all nervous tissue is being reached. But, if penicillin does not appear in the C.S.F., one can say that not all nervous tissue is being reached. It is therefore reasonable, unless toxic symptoms appear, to use doses which would be sufficient to cause spirochæticidal concentrations of penicillin—at least 0·01 unit per ml. (Eagle and Musselman 1944)—to appear in the C.S.F. of almost all normal persons, not merely all patients with neurosyphilis. Our material, together with that of previous investigations, provides evidence on which to found a rational scheme of dosage. Schwemlein et al. (1946) gave doses of 10, 15, 20, and 25 mega-units by continuous intravenous drip over a period of twenty-four hours. The mean C.S.F.-penicillin levels reached with these doses were respectively about 0·03, 0·05, 0·04, 0·20 unit per ml. In the present investigation intramuscular doses of 0·5, 1, and 2 mega-units gave six hours later to C.S.F.-penicillin levels of 0·05, 0·[illegible] and 0·11 unit per ml. respectively. Comparison of [illegible] figures with those of Schwemlein et al. suggest intermittent dosage may be more effective than [illegible]ous intravenous infusion in breaching the C.S.F. [illegible] If this is so, the C.S.F.-penicillin level probably depends more on the height of the peak serum-penicillin level than on the time for which an effective serum-penicillin level is maintained. For example, to reach a relatively inaccessible tissue, in this case the C.S.F., a serum-penicillin level of 25 units per ml. maintained for an hour is as effective as one of 10 units per ml. maintained for several hours. Such a hypothesis would explain also our finding that repetition of the same dose does not greatly increase the C.S.F.-penicillin level.

Of 18 patients without demonstrable organic disease of the central nervous system who received 0·5 mega-unit of penicillin intramuscularly, 11 (63%) showed C.S.F.-penicillin levels higher than 0·037 unit per ml. Twice this dose, 1 mega-unit, would probably produce this level in almost all persons. Doses of 2 mega-units are well tolerated. In all our patients receiving 1 mega-unit or more, penicillin was found in the C.S.F. It thus seems that doses of 1 and 2 mega-units may justifiably be used, and are necessary to breach all normal barriers.

As regards the time-interval between doses, it seems improbable that the C.S.F.-penicillin level will fall as long as the blood-penicillin level is higher than it. When a dose of 0·5 mega-unit of penicillin is given, the blood-penicillin level is still 0·1–0·5 unit per ml. four hours later, justifying spacing of doses by at least this interval. If a limited amount of penicillin is to be used, large well-spaced doses are probably more effective in breaching the barrier than are small frequent doses.

SUMMARY AND CONCLUSIONS

The reliability of a serial-dilution method for the assay of penicillin in the C.S.F. was investigated.

The method was used to assay 152 samples of C.S.F. from 111 patients, who included a group of cases of parenchymatous neurosyphilis. The samples were obtained by ventricular, cisternal, and lumbar puncture, usually four hours after a dose of 0·5 mega-unit of penicillin.

A single intramuscular dose of 0·5 mega-unit produced a bactericidal C.S.F.-penicillin level in 70% of the patients.

After such doses penicillin appeared in the C.S.F. of persons with no demonstrable intracranial disease.

Penicillin was found in the C.S.F. of one patient fifty minutes after intramuscular injection. Four hours after injection penicillin is probably distributed fairly evenly throughout the C.S.F.

Those diseases which cause excess protein to appear in the C.S.F. also cause greater permeability of the blood-C.S.F. barrier to penicillin. High concentrations of penicillin were found in three cerebral gliomatous cysts. Thus penicillin apparently penetrates much more readily tissue whose vascular structure is damaged than it does normal tissue.

Barrier permeability tends to be higher in the elderly.

High or low C.S.F. pressure does not seem to affect permeability.

If a limited amount of penicillin is to be used, large well-spaced doses are probably more effective than small frequent doses for achieving high C.S.F.-penicillin levels.

We wish to thank Mr. Wylie McKissock for permission to use samples of C.S.F. from his neurosurgical patients at the Atkinson Morley Hospital; Prof. A. J. Lewis and Prof. S. Nevin, of the Maudsley Hospital, for much very kind help and advice; and all members of the staffs of the two hospitals

Control of hypertension in advancing years

trade mark **'THEOGARDENAL'** brand

theobromine and phenobarbitone tablets

Combining the cardiac stimulant action of theobromine with the sedative effect of phenobarbitone, 'Theogardenal' is of particular value in alleviating the symptoms of hypertension and especially in lessening the distressing effects of cerebral vascular changes. Middle aged and elderly patients experience marked relief from giddiness, headache, loss of memory, and insomnia. The drug has no cumulative effect and is well tolerated over lengthy periods

Containers of 25, 100 and 500 tablets
(Each tablet contains theobromine gr. 5 and phenobarbitone gr. [illegible])

Our Medical Information Division will be pleased to send a copy of the medical booklet 'M&B Barbiturates in General Practice' on request

manufactured by **MAY & BAKER LTD**

PHARMACEUTICAL SPECIALITIES (MAY & BAKER) LTD., DAGENHAM

For a Salt-free Diet . . .

NEO-'SELAROM'

Sodium restriction is now regarded as an important part of the modern treatment of cardiovascular disease, and is also recommended in dermatology, hypertension and certain complications of pregnancy

Neo-'Selarom' is a completely sodium-free condiment which may be used like ordinary table salt, and will spare the patient the misery of unseasoned food

the present state of prognosis and therapy of mental illness, leaning rather heavily but by no means exclusively on the German literature.

Brain and Behaviour

Induction as a Fundamental Mechanism of Neuro-psychic Activity. N. E. Ischlondsky, M.D. London: Henry Kimpton. 1949. Pp. 182. 21*s*.

In this monograph the author presents personal observations, mainly on vision and sensation, which serve to elaborate his views on the phenomena of "induction." Induction, in the sense of the monograph, covers the statement that "every manifestation of a nervous process leads, under certain well defined conditions, to the appearance of an opposite process." This conception is elaborated, from simple observations upon the visual responses to complementary colours, to those of group behaviour. Dr. Ischlondsky noticed in a mass experiment that when he propounded one point of view to an audience, 80% criticised his thesis; when he propounded the opposite point of view to another similar audience, 72% criticised *that* thesis. Though he contends that "there can hardly be a more convincing proof, or a more eloquent illustration, than this of the powerful effect of induction," other and equally eloquent interpretations will occur to the reader.

Dictionary of Genetics

R. L. Knight, D.Sc., Ph.D., senior economic geneticist, Empire Cotton Corporation and Sudan Government. Waltham, Mass.: Chronica Botanica Co. London: W. Dawson & Sons. 1948. Pp. 183. $4.50.

The terminology of genetics, with its "chiasmata," "heterotetraploids," "karyoplasm," "phenotypes," and "zygotene," not to mention "xerocleistogamy" and "merostathmokinesis," is forbidding even to the experienced pathologist. In his dictionary Dr. Knight makes a praiseworthy first attempt to ease the task of a relatively uninitiated reader of genetical literature. Some notes on statistics are provided in an appendix. Since Dr. Knight writes as a plant geneticist, the book shows botanical bias in defining medical terms like "thalamus" and "placenta"; for the human geneticist it may be used to amplify but not to replace existing medical glossaries.

Patologia Psicosomatica

Dr. J. Rof Carballo. Madrid: Editorial Paz Montalvo. 1949. Pp. 818. Ptas 200.

In this large volume Dr. Rof Carballo reviews the extensive literature dealing with the response of bodily structures to emotional changes. The first twelve chapters are concerned with a general appraisal of psychiatric theories against the background of structure, while the remaining major part deals with the responses of individual systems of the body. This section of necessity deals with such a wide field of medicine that it can be used to support the contention that the adjective "psychosomatic" indicates an approach to, rather than a division of, the subject. The author has supported his thesis with a large and well-balanced bibliography as well as by many personal observations. It is a fine reference work, but the fact that it is in Spanish will limit its use.

Photo-electric Methods in Clinical Biochemistry

G. E. Delory, M.Sc., Ph.D., assistant professor of biochemistry, University of Manitoba, Winnipeg. London: Hilger & Watts. 1949. Pp. 90. 15*s*.

This small handbook gives briefly the theory on which photo-electric methods are based, detailed instructions for the use of the two photo-electric colorimeters manufactured by Messrs. Hilger, and accounts of several estimations in clinical biochemistry with techniques based mainly on those developed in Prof. E. J. King's department at the Postgraduate Medical School of London. Photo-electric methods are becoming more popular, and this handbook will therefore be welcomed. It is unfortunate that the instructions are applicable to the instruments of only one firm, but there will be little difficulty in adapting the methods to whatever type the reader has in use.

Occupational Therapy Source Book

Editor: Sidney Licht, M.D. Baltimore: Williams
Wilkins. London: Baillière, Tindall, and Cox. 19
Pp. 90. 5*s*. 6*d*.

The use of occupation in the treatment of the ins
has been strongly advocated by some of the f
writers on psychiatry since the end of the 18th centur
There are here extracts from the Frenchmen Pi
Esquirol, Leuret, and Voisin; from the America
Benjamin Rush, Kirkbride, and Eva Reid: from Ke
and from William Halloran of Cork and Samuel Tu

perhaps not wholly beneficial.

Neurology

(4th ed.) Roy R. Grinker, M.D., director of the institu
for psychosomatic and psychiatric research and trainin
Michael Rees Hospital, Chicago; Paul C. Bucy, M.D
professor of neurology and neurological surgery, Unive
sity of Illinois. Oxford: Blackwell Scientific Publication
1949. Pp. 1138. 63*s*.

This is now a standard textbook of neurology, thou
its size and the detail of its descriptions make it unsu
able for the junior student. This edition differs from i
forerunners both in subject matter and format. It h
been reset and extensively revised, and in both respec
improved. Clinical neurology is now such a vast an
rapidly changing subject that advanced textbooks a
apt to be cumbersome. Dr. Grinker and Professor Buc
aware of this danger, have pruned as they have add
new material. One of them has a psychiatric and t
other a surgical approach, and it may be this combinati
that gives the book its breadth of interest. Function
not submerged in structure, though some of the
ical aspects of neurology receive more attention th
disorders of function. The book is more suited to
neurological surgeon than the neurological physician
but the best neurological surgeons emerge throu
physiology and medicine, and the most enlighten
neurological physicians have had experience of t
surgical method. Many will use this as a referen
volume, and it will also be popular among senior student

Recent Advances in Oto-laryngology (2nd e
London: J. & A. Churchill. 1949. Pp. 395. 24*s*.).—Th
delightfully readable book has been extensively revised a
new chapters introduced. Some unevenness is noticeabl
particularly in the theoretical sections, possibly owing t
Mr. R. Scott Stevenson's anxiety not to omit any reasonab
contribution to a given problem. There hardly seems muc
place in this sort of book, for example, for a detailed a
illustrated account of a technique of tonsillectomy. The bu
of the more modern references are English and North America
The advanced student will find a *great deal* to interest a
instruct him and the practising specialist will derive muc
profit and stimulation in reading the discussion of any proble
in which he is particularly interested—so well covered is eve
phase of the specialty.

Training for Childbirth (4th ed. London: J. &
Churchill. 1949. Pp. 192. 10*s*. 6*d*.).—Nowadays, wh
so many people are talking about analgesia in childbirth,
is particularly interesting to read the fourth edition of Mi
Minnie Randell's excellent exposition of the advantages o
unsedated delivery. She writes as a physiotherapist an
a nurse, and shows how the mother, through education an
training, can enjoy the birth of her child without sedative
The book is written for mothers, and includes good chapte
on anatomy and physiology and on the preparation fo
breast-feeding. Miss Randell's diaries might benefit fro
editing; they would then show more clearly how a knowled
of the bodily processes in delivery help the mother so greatl
and would lose the somewhat macabre flavour they have a
present. The illustrations are good and clear, and the exercis
given are related wherever possible to ordinary househol
duties. It is a book to be read by all who are interested i
childbirth, including members of *Parliament*.

THE LANCET

LONDON: SATURDAY, OCT. 8, 1949

Misadventure in Prophylaxis

ATH from disease is natural, and, sooner or later, expected. But death arising through medical s to prevent disease is unnatural and on the of it unnecessary. Fatality has no place in ntive medicine and comes as an unforeseen dy. A painful example is the death "by lventure" of three Hornsey children who oped acute hepatitis some eight weeks after lation with human serum to prevent measles. St. Pancras coroner, after searching questions, rated the doctors, the technique, and the ges, and attributed the fatal hepatitis to the nce of a virus in the serum used.[1]

e lessons that may be learnt from this disaster arious. The facts are that since 1941 the Medical rch Council has issued whole adult serum in of 5–10 ml. for measles prophylaxis or attenua- 30,000 healthy children, contacts of measles at nurseries, have with their parents' consent injected with such doses intramuscularly: and 1946 a planned investigation has been in progress ie comparative preventive value of a British ia-globulin and of pooled serum. Until last h no cases of jaundice were observed among f these inoculated children. Actuarily, therefore, isk of such prophylaxis has proved extremely , while the advantage gained, though less easily uted, may have been very substantial. In 1947 gland and Wales 576 children under five years of ied of measles or its immediate complications: young children the disease is still one that is worth preventing or modifying. Up till now, ast, most doctors would have been prepared ke the associated risk if their own children were ed to the dangers of measles in a community as a nursery school. But does this imply that its should be urged to permit their healthy en to be inoculated? So long as there is some ble risk to the normal person's health in accepting ylactic measures, this risk ought to be explained. whereas it is easy to adopt an authoritarian ide ("the doctor knows best") it may often be ult to make the position reasonably clear to its without frightening them into refusing the its.

e hazards are those inherent in the injection of in blood products. The past ten years have all too many reports of jaundice, sometimes fatal, developing 50–180 days after injection of convalescent serum, of yellow-fever vaccine suspended in human serum, and of whole blood, plasma, or serum, or after intravenous injection of drugs with syringes contaminated internally by traces of blood from other patients. This "homologous serum jaundice" is attributed to the presence of a living virus in the donor's blood, and though the proportion of donors harbouring the virus may be no more than 0·35%[2] the danger is magnified when individual donations are pooled, as in preparing plasma and serum. Unfortunately there is as yet no practical means by which blood can be routinely tested for the presence of virus: but efforts have of course been made to minimise its spread. Thus at regional transfusion centres steps have been taken to lower the risk that arises from pooling: the maximum number of donors whose plasma or serum is mixed is limited to ten. Further the centres will not accept blood from a donor who gives a history of jaundice within the previous twelve months—a time limit imposed on experimental evidence that blood from recovered cases of serum jaundice did not infect human volunteers more than two months after the end of the illness. The batch of blood used to prepare the serum which infected the Hornsey children was prepared from a group of 60 donors of whom it is now known that 5 had suffered from jaundice at periods varying from five to fourteen years before being bled. This not only illustrates the extension of risk by having a large pool but also suggests the need to revise the rule permitting acceptance of blood from donors only one year after suffering from jaundice. (We wonder incidentally how many of the hundreds of thousands of donors bled annually have been, or are, asked specifically whether and when they have had this disease.) On the other hand in LEHANE's survey[2] follow-up of donors contributing to icterogenic plasma pools revealed only one who had had jaundice—and that was three months after being bled. The donor with a subclinical attack or incubating the disease may well be the more serious menace, and at present there is no way of detecting such people. All this being so, any doctor who uses a blood product must know exactly what he is giving and be aware of the dangers. Bottles of plasma, for therapeutic use, already bear a warning that the risk of hepatitis following its infusion is "up to 10%,"[3] and this must be a very considerable deterrent to its use where life can be saved by any less dangerous means.

What other precautions are open to us? American work suggests that hepatitis virus in a blood product can be inactivated by exposure to ultraviolet light, and this may make it possible to provide a safe plasma. From the standpoint of prophylaxis it is more important to know that gamma-globulin prepared from serum by fractionation is believed to be always free from virus. If experience confirms this, the fractionated product must as quickly as possible supersede whole serum; and we hope that it will soon be generally obtainable in this country, though it must be remembered that still more donors will be needed to provide it.

Left Ventricular Failure . . .

In manifestations of left ventricular failure the action of Cardophylin may be of great value. This action is probably two-fold, consisting of an increased blood supply to the failing myocardium as a result of coronary vasodilatation and a direct stimulating effect on respiration.

Cardophylin

(THEOPHYLLINE-ETHYLENEDIAMINE)

VASODILATOR, RESPIRATORY STIMULANT AND DIURETIC

In tablets for oral use; ampoules for intravenous and intramuscular injections, suppositories. Literature and samples on request.

nt issue two more strange instances of poisoning ad are described: **Kennedy** and **Lynas** report case of a woman of 46 who had generalised iative dermatitis, treated with lead-acetate ings. It was estimated that about 1400 mg. organic lead had been in contact with the skin ixteen weeks, though the dressings had actually applied intermittently over a period of seven hs. At the end of this time she developed mild intoxication which responded to treatment with onium chloride, parathyroid extract, and a alcium diet. It is assumed that lead acetate absorbed through the damaged skin. The rs refer to the animal experiments of **Laug** and ze,[1] who showed that the volatile organic lead pounds—e.g., tetra-ethyl lead—easily penetrated skin of rats, whereas the inorganic compounds through only in very small quantities. **Kennedy** **Lynas** do not mention that when wide areas of are smeared with lead compounds the fingers food may become contaminated, though clearly must be taken into account when tracing the by which the lead entered the body. Their le, however, will draw attention to the harm h may result from the protracted contact of lead pounds with a damaged skin.

more serious source of lead poisoning is discussed ordon and **Whitehead**. They report a case of encephalopathy associated with rickets in a onths-old infant whose mother had used lead le-shields during lactation. The infant had been itted to hospital with a provisional diagnosis of rculous meningitis. The main signs of chronic poisoning in infants are fretfulness, irritability, lessness, convulsions, vomiting, a tense fontanelle, opisthotonos; there may also be ocular changes as papillœdema, optic atrophy, and optic itis. The blood may show anæmia, punctate philia, and reticulocytosis, and the cerebro- al fluid is under increased pressure. Radio- hy of the long bones usually reveals a dense line nd on the epiphyses due to the deposit of lead salts ese areas. The first case of this sort recorded seems ave been that of **Cadman**,[2] who in 1902 described finite example in a boy aged 5 weeks. Here the her's milk had clearly dissolved some of the lead ld. In the U.S.A. similar accidents were reported 926 and 1939.[3] **Gordon** and **Whitehead** point that the infant might have absorbed lead by of three means: (1) ingestion of metallic lead a deposit on the mother's nipple; (2) ingestion deposit of lead salts on the nipple; and (3) rption of lead from the mucosa of the nipple excretion in the breast-milk. Whatever the te of absorption, lead nipple-shields are manifestly gerous and their use should be abandoned. In tter on another page Dr. **Helen Mackay** and **Donald Hunter** appeal to doctors and midwives lo all they can to abolish the use of this dangerous al in nipple-shields for nursing mothers. "No ther," they say, "would risk using them if she w the facts." The Ministry of Health in a ular letter, dated Sept. 7, also emphasises the ent importance of discouraging the use of lead nipple-shields; and notices are being sent to all doctors, chemists, and suppliers of surgical appliances.

The prognosis of lead poisoning in infants is bad. **Byers** and **Lord** [4] have shown that lead poisoning in childhood has a severe deleterious effect on mental development. Of 20 school-children who had recovered from lead poisoning, only 1 made satisfactory progress at school; all the others had behaviour difficulties, with loss of normal inhibition, and were unreliable, cruel, and impulsive. **Alice Hamilton** [5] quotes the work of **Riggs** and others, who found a significantly higher concentration of lead in the kidney and the pituitary in 95 patients where death was not adequately explained by clinical or necropsy findings, compared with 40 where the cause of death was clearly defined. In the first group there have been signs and symptoms suggesting that lead encephalopathy was the cause of these unexplained deaths. Again, the work of **Nye**,[6] in Queensland, showing that lead poisoning in childhood leads to a high incidence of chronic nephritis in later life, should be borne in mind. The sources of lead poisoning are numerous and the long-term effects disastrous, particularly from intoxication in childhood. One source of poisoning can instantly be eliminated by abolishing lead nipple-shields.

Annotations

PUBLICITY AS A PENALTY

Only last week we commented [7] on a letter from the Ministry of Health warning executive councils of the care they should take in giving publicity to disciplinary proceedings. The Minister's view was that "at no stage should mention be made of the names of the parties to the proceedings or of other particulars which might lead to their identification." Hence it was surprising to find the Ministry itself a few days later issuing simultaneously to the medical and to the lay press an account of the proceedings and findings of the first tribunal to be convened to hear a case against a medical man and including in that account the full name of the medical man against whom the proceedings had been taken. The inclusion of his name seems all the more unfortunate in view of the tribunal's decision that "all those facts which it has found to be established amount to a single incident, and the tribunal has come to the conclusion that, despite the very grave and serious view which it takes of the matter, it is not justified in saying that this single incident is such as to cause the continued inclusion of the respondent in the said medical list to be prejudicial to the efficiency of the General Medical Services." The doctor is to be allowed to continue in his practice, but that practice must now be gravely damaged by the harmful publicity given to his offence by the lay press last week.

Was this publicity necessary? Would not a record of the case without names have sufficed to show both layman and doctor that justice had been done? Full details of the case, preserving anonymity, had been published earlier in the year after the hearing by the medical services committee. Last week's report added only the reasoned findings of the tribunal, and the doctor's name. None will deny the need to give publicity to the tribunal's attitude to the case, but the regulations [8] leave the Minister free to publish any decision of the

Aerosols by Inhalation

FROM its humble rôle in the palliation of asthma, aerosol inhalation has evolved into a means of administering antibiotics and other chemotherapeutic substances. Quantitative work during the late war[1] was followed by clinical trials at home and abroad; and now certain special indications and limitations are recognised.

The aerosol offers attractive opportunities for laving the respiratory mucosa with drug solutions at concentrations which are not merely bacteriostatic but germicidal; for example, a neutral solution of 10% sulphathiazole (in the form of 22·5% 'Soluthiazole') containing 50,000 units of sodium penicillin G per ml.[2] should normally suffice to destroy a wide range of infective organisms. Moreover, by this method vulnerable compounds enter the body through the lungs without exposure to destruction by the digestive juices; and the drugs do not disturb the natural balance of the intestinal flora—a matter of some importance since nicotinic-acid deficiency may result from inhibition of colonic bacteria by antibiotics administered by mouth.

It is now known that a portion of the inhaled drug is absorbed quickly and exerts a systemic action, while an appreciable fraction remains trapped for many hours in the sputum and pulmonary discharges, where it continues to produce its specific effects. This partition probably accounts to some extent for the wide individual differences of drug concentrations in the blood and urine during any given inhalation routine. The aerosol method is especially applicable to the treatment of diseases of the bronchial tree, where direct access permits of intensive topical therapy. WILSON and his co-workers[3] have shown that in experimental pneumonia penicillin is just as effective, dose for dose, when inhaled as it is when given by injection, even though the final airways are blocked so that the drug can reach the infected zone only after absorption into the blood-stream. Thus bronchopneumonia, especially in young children, can hopefully be added to the selected list.

Comparison of results is difficult, for aerosols are of various types and are somewhat unstable, and the techniques and devices for administration are many. It is hardly surprising that the status of inhalation therapy has still to be defined. GÖSTA ROOTH's[4] recent quantitative survey is, however, particularly welcome. He has carefully explored the quantitative aspects of mist production and preservation and of bronchial penetration and deposition, by physical and chemical measurements of the mists themselves and by analyses of the urine, blood, and sputum of his patients. There can be little doubt that for administering chemotherapeutic substances in pulmonary diseases, nebulisation by hand-bulb is totally inadequate. Not only must the aerosol be of a particle size suitable for ingress to the desired depth, but the weight of drug carried by these small particles must be as great as possible because even the densest mists are weak compared with simple solutions. The length of each inhalation session, which is also of practical moment, depends on the volume of mist taken in with each breath. An upper limit is set by the pulmonary ventilation-rate of 6–10 litres per minute, and to avoid the tedium of lengthy administration this should form the lower limit of production by the machine. There seem, moreover, to be some slips 'twixt cup and lip. The amount of solution leaving the nebulising phial is by no means the same as the amount actually passing into the trachea. Unless the conduits and the face-piece or nose piece are streamlined and the expired air is prevented from buffeting against the oncoming mist, the droplets coalesce into drops and deposit in the external airways on the face, or in the anterior part of the nasal passages. The interposition of a humid space between the delivery-tube and the patient—as when the mist is puffed into an oxygen tent—causes a rapid increase in the diameter of the droplets and so promotes deposition. The same unfortunate loss takes place when ice is used to extract excess moisture from an oxygen tent. Water-vapour and aerosol precipitate at the dew-point.

Considerable technical knowledge is needed by all who would practise the method successfully, and much still remains to be done by the instrument makers. Jets are readily blocked by even the finest floating particles; the need is for a simple apparatus with an accessible nebulising device which can be quickly cleaned and which will produce denser mist at full ventilation-rates delivered to the patient without loss. It should then be possible to abort the annual attack of recurrent bronchitis, to control the acute phases of bronchiectatic inflammation, to increase the safety of operations on infected lungs,[5] and to eliminate the secondary septic complications of influenza and other pulmonary virus diseases.

Dangers of Lead

THE history of man's use of lead has a respectable antiquity, for the containers for the plants in the hanging gardens of Babylon were of lead, and it is mentioned by HIPPOCRATES as a cause of poisoning. It also has an uncomfortable modernity, since it still poisons people in strange and unsuspected ways. In industry lead and its salts have many uses, but the risk is recognised; poisoning is now rare, and when it does arise it is much less severe than fifty years ago. At the beginning of this century there were over 1000 industrial cases yearly; now the number rarely reaches double figures. It is from the non-industrial uses of lead that bizarre cases of poisoning crop up from time to time. The actor, for instance, may be poisoned by grease-paint containing lead; a bullet in the lung may set up slow poisoning; curry powder has occasionally contained lead chromate and caused abdominal pains in those who consumed it; the "poisoned rain drops" on the white verandahs of Queensland houses produced many cases of lead poisoning and nephritis in children; the lead pipes through which the cider and beer is drawn from cellar to bar have caused Saturday-night colic; the peat acids in a town's water-supply can dissolve lead salts from the pipes through which it passes and poison large numbers of people; and so on. In the nd that would involve the addition to the central of many more millions of pounds even than the ained, and perhaps unattainable, sum already . by the General Medical Services Committee. It ses that executive councils should be empowered vance money for the purchase of cars, equipment, remises to enable young doctors to start practice eas where they are needed, recovering this money egular deductions from the quarterly cheques. unhappy about the varying conditions under the fixed annual payment is made in different , and suggests that the Medical Practices Committee d determine and make these grants, drawing the sary monies from the central pool or from a separate It would like to see a limit placed on the time g which a principal can continue to enjoy the its of employing an assistant, and it believes that having had an assistant for two years he should r admit a partner or reduce his list—though rently this rule would be waived where an assistant ployed, not to help cope with an inflated list, but r because the principal is infirm or old.

ese are but a few of the suggestions thrown out in mphlet full of material for thought and debate. of the recommendations made are already being led; some are not yet practicable: and some may r be practicable. But in posing the problems and esting possible means of resolving them the Medical titioners Union has done a service.

INFLAMMATORY STASIS

1931 Kreyberg and Rotnes[1] demonstrated stasis in ear vessels of the rabbit following the trauma pro- d by freezing. First lithium carmine was used to ur the blood-plasma; then a stick of carbon-dioxide was applied to the ear in several places. In a few tes the traumatised regions were pinker than the of the ear—an appearance due chiefly to filling of dilated vessels with flowing blood. Twenty-four s later indian ink was injected into the heart, and it the entire vascular system except these pink matised regions, in which the blood-vessels were dilated but the blood was in stasis. This stasis is due to thrombosis but to the solid packing or con- ination of the red blood-cells. These long columns onglutinated red cells cannot readily be moved along vessels in which they lie, so that anoxæmia and ndary necrosis may develop in their field of supply.[2] se changes, so clearly demonstrated in relation to zing, play their part in inflammatory reactions to r noxious agents; and much of the tissue damage in mmatory foci may result from anoxia secondary tasis.

rofessor Kreyberg's letter in this issue draws attention ur lack of knowledge of the pathogenesis, prevention, treatment of prestasis and stasis. The commonly view of the pathogenesis of stasis is that plasma s through damaged capillary walls, leaving the vessels d up with blood corpuscles. However, Lewis[3] found t after histamine damage to capillary walls, fluid ely resembling plasma leaks out of the capillaries; yet stasis does not ensue. It appears therefore that plasma leakage is not the only factor concerned in production of stasis. During the second world war problem arose of treating people whose extremities been severely chilled but not frost-bitten. Removal m the cold environment was often followed by patho- ical changes in their feet or hands, including even grene. Probably vascular stasis plays a considerable rt in the development of this syndrome, which came to be known as immersion foot[4]; and with greater knowledge of the prevention and reversal of stasis more effective treatment might have been devised.

UNKNOWN QUANTITIES IN JUVENILE DELINQUENCY

EVERYBODY feels competent to give advice about a bad child. In March of this year, the Home Office and the Ministry of Education jointly set out[5] the best available opinion on possible remedies for juvenile delinquency. The provisional figures for 1948, they said, showed an increase of 26% for children under fourteen, and of 23% for children between fourteen and seventeen, found guilty in magistrates' courts of indictable offences. The remedies suggested—which included secure affection, a stable environment, better opportunities for leisure occupations, proper training and guidance, special education for the handicapped, and guidance for those starting work—have wide support among knowledgeable people, and may well be the right ones, even if they are not particularly easy to achieve. But at a conference[6] on Oct. 1, on the scientific study of juvenile delinquency, many speakers pointed out that we really have very little scientific evidence to go on.

A broken home is a common finding in the history of delinquents; yet under this heading, Dr. Hermann Mannheim remarked, we lump together many different situations: the break may be due to death, or to desertion. In the same way a "gang" may be a band of boys collaborating in an isolated offence, or a semipermanent association of unruly young people. Boys who belong to clubs are less often in trouble than those who do not; but it may be that clubs attract boys who would not in any case get into trouble. Again a "club" may be a good influence or a poor surrogate for the real thing. Opinion about the influence of films fluctuates between the old theory of "imitation" and the newer theory of "healthy outlet." Prof. T. S. Simey quoted the view of the late Dr. Kurt Lewin, that "it is usually easier to change individuals formed into a group than to change any one of them separately," and suggested that a better social setting for family life might itself reduce delinquency. At present, as several speakers noted, our information is confined to the study of delinquents brought into court; we have no means of comparing them with their fellow citizens, or deciding to what extent the rest of us show delinquent tendencies. But even what evidence we have is not widely accepted, even in magistrates' courts. We know, for example, that first offenders are best dealt with by methods other than imprisonment; yet the report of the Prison Commissioners,[7] for 1948, deplores that, in 1947, 712 youths and 88 girls were sent to prison for their first proved offences. In fact, "evidence," as Mr. Alec Rodger said, "is not necessarily acceptable because it is indisputable and cogently presented. Professor Simey remarked that we are all afraid of the latent delinquent in ourselves. There are therefore good grounds for Dr. Denis Carroll's plea that all those concerned with the disposal and treatment of delinquent children should read up their subject.

The general feeling of the conference, later embodied in a resolution, was that research on a large scale should be initiated in consultation with all the professions concerned. Dr. Carroll put the case for setting up a Delinquency Research Council, or a council with an even wider scope to cover social research in general.

tribunal "in such manner as he thinks fit." The question therefore arises whether the abandonment of anonymity was deliberate, and, if so, whether this decision was taken because it was felt that the doctor's culpability was too great justly to allow of his escaping scot-free. A penalty of unpredictable severity has in fact been imposed on him, and this is a bad precedent to come out of the first case to be tried by the tribunal. Lest it should become sanctified by recurrent use it might now be well if the regulations could be looked at again, and means found whereby the tribunal or the medical services committee could be empowered to impose one of the lesser penalties prescribed in the regulations[9] on an offender whose offence, though regarded as culpable, is not eventually deemed sufficient to warrant the removal of his name from the medical list.

COMPOSITION OF GASTRIC JUICE

Of late there has been much progress towards a clearer understanding of the bewildering variations in the composition of gastric juice; and a review by Franklin Hollander[10] should encourage the clinical application of this work.

Advances have been brought about by means of improved chemical methods and the statistical analysis of results. Chemical studies of the organic material in the gastric juice have made the subject more complex; for example, the proteolytic activity of the gastric juice must now be regarded as probably due to a mixture of enzymes, and Glass and Boyd[11] have divided the gastric mucus into two chemically distinct fractions. On the other hand, the statistical analyses which stem from Hollander's pioneer work have made it possible to predict with some certainty the relations between the concentrations of the main inorganic constituents. In man and in animals the composition of pure gastric juice varies widely. It may be acid, with a pH as low as 0·9, or it may be as alkaline as the blood, with a pH of 7·4; and the concentration of chloride may lie between 120 and 170 milli-equivalents per litre. The main bulk of the inorganic constituents apparently originates in two components of fixed composition—a secretion containing a concentration of about 170 milli-equivalents of hydrochloric acid per litre, and an alkaline secretion. When the rate of secretion of the gastric juice rises, the increase is mainly in the acid component; thus when the rate of secretion is high, the proportion of the alkaline component is small so that the concentration of acid in the gastric juice is nearly as great as the concentration in the pure acid component. The alkaline component contains less chloride than the acid component, and so a fall in the proportion of acid component is accompanied by a corresponding fall in the concentration of chloride in the mixture. In a neutral gastric juice, the acid component being neutralised by the alkaline component, the concentration of chloride is about 120 milli-equivalents per litre; this chloride is known as "neutral chloride" since it is in electrical equilibrium with alkali metals. At the other extreme, when the gastric juice is very acid most of the chloride is in electrical equilibrium with hydrogen ions and the concentration of neutral chloride is as low as 3–5 milli-equivalents per litre.

Hollander obtained confirmation of the two-component hypothesis by plotting the concentration of acid in the gastric juice of dogs against the corresponding concentration of neutral chloride; the points fell on a straight line. By extrapolation of the straight line he found the expected concentration of acid in the gastric juice when the concentration of neutral chloride was zero. This was about 170 milli-equivalents of hydrogen ion per litre, which he assumes to be the "primary acidity" of the parietal component. Hollander and his workers[12] have also been investigating the alkal component. The cells producing this component, wh are not confined to the pyloric portion of the mucos are specifically stimulated by the local application eugenol (*B.P.C.*).

It appears that the membrane of the parietal cell permeable only to water, hydrogen ions, and hal ions. The hydrochloric acid is thus secreted as at a concentration which is slightly hyperosmotic the blood. Recent studies have shown that the metabolism of the parietal cells is not sufficient to the hydrogen ions excreted, which are withdrawn the form of bicarbonate from the blood flowing th the gastric mucosa.[13] These investigations may reveal some specific inhibitor of acid pro therapeutic tool which would be welcome in the treatment of peptic ulceration. Hitherto most clinical investigations have been concerned with the concentration of acid and to a less extent pepsin, in the gastric contents. The distinction between resting juice, a mixture duodenal contents, saliva, and gastric secretion, digestive gastric contents in which the gastric juice is mixed with food, and pure gastric secretion has not impressed itself on all clinical workers. The day is not far distant, however, when the gastric secretory response will have to considered in terms of the separate contributions from the various types of cell in the gastric mucosa.

ENTRY INTO PRACTICE

THE Medical Practitioners' Union has circulated to the profession a pamphlet which, though chiefly concerned with the difficulties encountered by entrants into general practice, also touches on some of those facing the would-be consultant.

Contrasting the material prospects of general and specialist practice, it shows that even if the general practitioner achieves a maximum list of 4000 patients—a number which the M.P.U. regards as much too large—his net income will still fall short of that of the least of his contemporaries who has achieved consultant status. Few general practitioners, however, are likely to acquire as many as 4000 patients even in the underdoctored areas; for the existing large practices are preserved by the automatic transfer of each deceased or retiring doctor's list to a single nominee—often a partner or assistant. The M.P.U. suggests that, instead of continuing this custom, the executive councils should be required to break up practices so that only a portion (varying from a quarter to a third) is automatically transferred to the doctor nominally taking over the practice, the remainder being divided by the allocation committee among neighbouring doctors with small lists, and—where extra doctors are needed—among invited newcomers. This, it thinks, might do much to help and encourage men who are now struggling, and might also allow of the easier introduction of new doctors into underdoctored areas. Despite these merits, however, the suggestion will meet with opposition, for it runs counter to the policy so far observed by the Medical Practices Committee, who deem it their duty as far as possible to preserve the identity of existing practices, and who agree only in special circumstances to the dispersal of existing lists among several doctors. Moreover, executive councils and local medical committees—which are jointly responsible for providing the allocation committees—are chary of using their powers of allocation, and much prefer that patients shall be given, and shall make, their own choice of doctor.

The M.P.U. favours a sliding capitation fee, and still, we find, adheres to its opinion that the proper fee should be 30*s*. for the first 2000 patients and 20*s*. thereafter—a

THE STUDENT'S OBJECTIVE *

Sir Hugh Cairns
K.B.E., M.A., D.M. Oxfd, F.R.C.S.
NUFFIELD PROFESSOR OF SURGERY, UNIVERSITY OF OXFORD

r the beginning of an academic year, most of us, ils and teachers alike, are inclined to do a little ate stock-taking—to ask ourselves what we are ing at and whether we are going the right way ut it. I will try to help you in this process. My le qualification for doing so is that I have spent ctically the whole of the last 35 years working among ients in three continents, and during that time I e had the good fortune to know as teachers and eagues some very great men.

)ur medical world is in a state of rapid change. the one hand we have the National Health Service, ch is faced with the stupendous task of providing only doctors *and* nurses but also sufficient hospital s and good equipment to meet the needs of the ion's sick. On the other hand we have the changes ught by medical research and discoveries in the ic sciences, and these changes have become more nerous and more important in the last 30 years n they used to be. Think only of the effect of the overy of insulin and penicillin, and of the modern atment of anæmia. And that is not all, for looming ad are substances which will be effective in treatment of the various types of rheumatism and cer. You might suppose from this conjunction of nges and from what has been said about social licine and health centres that most doctors of the ire will spend their time in preventing disease, in ping people well. I do not think that things will n out that way. So far from reducing the hospital ulation these life-saving discoveries seem to increase need for yet more hospital beds. Beds are required, n for long periods, to treat patients who would have d but for the new remedies. And more often than these patients survive to get ill again on some future asion. Undoubtedly there is a big field to be developed prevention of disease and ill health, but for most of the main task of the future will be, as it has been in past, the care of sick people. And our main objective o become good doctors.

THE GOOD DOCTOR

Iow does one become a good doctor? When one tor says of another, "He is a good doctor," the rds have a particular meaning. You will hear the ression used not only about some general practitioners, also about some specialists. As I understand it ood doctor is one who is shrewd in diagnosis and e in treatment; but, more than that, he is a person o never spares himself in the interests of his patients; l in addition he is a man who studies the patient not y as a case but also as an individual.

)iagnosis and treatment are of course the basis of our rk with patients. We learn these subjects day in l day out as we walk the hospitals, and we have to s examinations in them. I do not propose to discuss m except to emphasise that after graduation none of is infallible; if we accept this fact, and are prepared go on learning, our mistakes will become less frequent d less serious.

How does one learn to devote oneself unsparingly to e's patients? You cannot get this from books or from formal clinical instruction. It is something which is passed on from one generation of doctors to the next, and the easiest way to acquire it is to work with a doctor who already has it in his blood. Lister, for example, was a good doctor: he used to visit his patients in King's every day, including Sundays, and his eminence and his preoccupation with research did not prevent him from showing great understanding and consideration of their feelings.

Your patients need from you more than diagnostic and therapeutic efficiency They do not come to you to be cured; they come to be relieved of their pains and other symptoms and to be comforted. Forced to choose, they would usually prefer a kind doctor to an efficient one. Never forget that the patient and his relations are usually frightened and anxious—upset in their normal life to such an extent that they are prepared to call *you* into their lives and to tell you the most intimate facts about themselves, though you may be unknown to them except as a member of an honourable profession. In their anxiety, especially when things are not going well for them, they may on rare occasions be rude to you and offend your dignity. This may be hard to bear, especially in the early days of one's medical life before one has lost one's self-consciousness at the bedside and has become wholly familiar with clinical technique. Under such trials you must humble yourself and continue to treat your patient with consideration and kindness, never forgetting for one moment that he is an anxious and overwrought person, and that in seeking your advice he has paid you the compliment of admitting you to his life and confidence.

Emergencies teach you how to devote yourself unsparingly to your patients and give that sense of urgency which all good doctors possess. To have a share in saving the life of a patient who is dying from hæmorrhage, peritonitis, respiratory obstruction, or meningitis is an essential part of the doctor's education. You learn then to observe quickly, to pick out the essential points of the illness, to apply first principles of therapy promptly, and to think clearly even when you are wracked with anxiety about the patient's welfare and your own responsibility for it. This anxiety which an emergency arouses in you is an inevitable and normal reaction—enough to numb all thought but for your training. Do not run away from it or seek to hide it beneath swagger and pomposity. Instead, familiarise yourself with it by staying with the patient at his bedside, by helping to nurse him, and by making accurate records of the events as they occur. Student nurses seem to assume their responsibilities in such cases more easily than do medical students; it is the difference between the practical and the theoretical approach to the problem of saving human life.

THE PATIENT'S PERSONALITY

The good doctor, whether general practitioner or specialist, is also a man who studies the patient's personality as well as his disease. In the past this was done by the light of nature: the good doctor started by being interested in his patients as individuals, and eventually his experience taught him to size up quickly most types of mankind and to know the reaction of each type to disease. This was instinctive unformulated knowledge. But now the position has changed, thanks largely to the medical work during the recent war, when we were fighting for our lives and it was realised that the adjustment of each individual to the conditions of war, and his capacity to work and fight, depended as much on his personality as on his physique.

The manifestations of an illness are much coloured by the patient's personality. What you are studying at
